DEPARTMENT OF ECONOMICS
SCHOOL OF SOCIAL SCIENCES
UNIVERSITY OF HYDERABAD
HYDERABAD 500 046

Dated: 30.06.1999

This is to certify that I, U. Hemantha Kumar have carried out the research embodied in the present thesis for the full period prescribed under Ph.D. ordinances of the University.

I declare to the best of my knowledge that no part of this thesis was earlier submitted for the award of research degree of any University.

Name: U. Hemantha Kumar 30/6/99

Enrollment No: 92SEPH06

Prof. M. ATCHI REDDY
(Research Supervisor)

Head of the Department: 5/7/99

HEAD
Department of Economics
University of Hyderabad
HYDERABAD - 500 134.

Dean of the School:

DEAN
School of Social Sciences

ACKNOWLEDGEMENTS

I would like to express my deep sense of gratitude to my supervisor, Prof. M.Atchi Reddy, Department of Economics, University of Hyderabad, for his constant encouragement and suggestion by providing concrete shape to my otherwise incoherant ideas. Without his help the thesis would not have been completed.

I would also like to thanks Prof.V.V.N.Somayajulu, Dean, School of Social Sciences, Prof. G.Nancharaiah, Head, Department of Economics, Prof.D.Narasimha Reddy, Prof.B.Kamaiah and Dr.V.Ratna Reddy for their help in my research work.

My thanks are due the commissioners, Andhra Pradesh State Archives, Hyderabad, Tamil Nadu State Archives, Madras for permitting me to use the documents in their respective repositories. I thank to the librarians of Indhira Gandhi Memorial Library, University of Hyderabad; Directorate of Economics and Statistics, Hyderabad; National Institute of Rural Development, Hyderabad; Technical Library, Secratariate, Hyderabad; Command Area Development, Hyderabad; Centre for Economic and Social Studies, Hyderabad; Osmania University, Hyderabad; Kannemara Library, Madras; Andhra Pradesh District Gazetteers, Hyderabad; and the Chief Engineers Office, Irrigation Department, Hyderabad.

I am glad to acknowledge the financial help in the form of fellowship received from the Indian Council of Social Science Research for the study.

My thanks from the bottom of my heart to Messrs. Md. Mustafa, Abdul Taha, Mallaiah, Subramanyam Raju, Murali Prasad, Sanatan, Madhava Reddy, Raheem, Narasaiah, Anil Kumar, Anand Sagar, Santosh Kumar, Dash, Saidulu, Kantharao, Anand Kumar, Davuluri, Mahmmed, who helped me more than one way during my study. I thank Mr.Narayana Gupta for rendering secretarial service.

I express my sincere thanks to my uncle, Mr.V.Pamidayya for his help, which enabled me in finishing this thesis.

I would be failing if I do not thank my mother, brothers, wife, and son for never withholding their emotional support all in my life.

U.Hemantha Kumar

CHAPTER-1

INTRODUCTION

The problem :

Development and management of irrigation would continue to be the important aspects of agricultural progress in India, since agriculture dominates in providing employment, and alleviating poverty and malnutrition.[1] India with a population of about 846 million (Census of India, P.15) may find it difficult to feed and cloth them without the corresponding rate of development in agricultural production in the next century.

India has to produce sufficient foodgrains and other agricultural products to ensure its population a reasonable level of consumption.[2] The country had adopted food self-sufficiency programmes especially of rice and wheat in the 1970's.[3] Irrigation is one of the chief inputs in increasing the volume of output and the case is strong in the production of rice, besides oil seeds and cotton. Therefore, output from irrigated lands should expand at a high rate so as to meet the projected food needs of the next few decades.[4] Poverty cannot be reduced without a rapid increase in the supply of foodgrains. The reason is that foodgrains makes up a large share of direct consumption in a low income economy.[5] The need to increase the ability of poor people to purchase food and the growth in foodgrains production can be sustained through irrigation and technological improvements. Irrigation can increase the direct employment in agricul-

ture to the poor workers. More important are the indirect effects on employment generated by spending the increased agricultural income.[6] The problem of food security, in particular is bound to assume growing importance for several reasons. Like most other densely populated countries, India faces a formidable challenge in providing food security to its population. Economic reforms, in general, and structural adjustment policies for agriculture in particular, that are designed to eliminate discrimination against agriculture, result in raising the prices of tradable agricultural commodities including foodgrains vis-a-vis manufactured goods (Bhalla G.S., 1994: p.28). The year-to-year fluctuations in agricultural and foodgrains production are very wide (ADB and IIMI, 1986, P.2).[7] Hence, what is needed is a search for realistic and pragmatic policies which can ensure food security and self-sufficiency in foodgrains. This underlines the importance of the development of water resources for irrigation in India.

At the time of Independence,[8] there were only two major storage reservoirs namely Mettur and Krishnarajasagar both on the Cauvery in South India. Thereafter, a number of major storage works were undertaken and the country embarked on a large number of irrigation projects. There had been considerable delays in their completion and the gestation periods were prolonged and extended beyond expectations. The major distortion came into play in the V Plan 1974-78 with as many as 73 new major and 331 medium irrigation projects were already under execution at the beginning of the V Plan (G.O.I, 1974-79 Appendix). Although the

number of new starts declined gradually thereafter, particularly in the 1980's, concerted efforts were not made to clear up the backlog. The spill over costs of irrigation projects continued to be high with the result that at the beginning of the VIII Plan 1992-97 as many as 182 major and 312 medium and 100 extension/renovation/modernization schemes were in the list of ongoing irrigation projects. About Rs.39,044 crores at the 1990-91 price level had spilled into the VIII Plan (GOI, 1993, P.58). The direct impact of such a large number of ongoing projects has been abnormal cost and they have overrun the allotted time. This has led to a slowdown in the rate of growth of foodgrains production in the country.

From the investment point of view, the lag in utilization of irrigation facilities had tremendous impact since the non-utilization of irrigation potential already created meant only investment without any financial returns. From Plan-to-Plan basis, the lag in the utilization had ever been increasing with the lag of 3.89 million ha. under major and medium, and 4.80 million ha. under major irrigation projects at the end of 1989-90. The investment cost of this potential that remained unutilized could be about Rs.12,580 crores (Water Management Forum, 1992, P. 823). However, besides such huge investment without any financial returns, there is also a financial loss of about Rs.4,300 per year on account of loss in incremental foodgrain production which would have otherwise come from this area, had it been under irrigation. This had discouraged further investment in agriculture.

An important point is that the percentage of costs recovered from farmers had been low. The revenue collection had not been sufficient even to cover the costs of operation and maintenance of the irrigation systems. One of the reasons for sub-optimal utilization of the existing irrigation facilities is the poor direct cost recovery from the sale of water. Financial difficulties in the irrigation sector are related to the fact that public irrigation is often heavily subsidized and the subsidies are often large in our country; and Government is not in a position to allocate financial resources further because of the overall budgetary constraints.[9] Under various political and administrative compulsions, the states have not been able to adhere to recover the revenue.[10] And as a consequence, the actual receipts vary from less than 1% to a maximum of 2.9% of the gross output. Sometimes, the existing projects are not maintained properly owing to resource crunch. The flow of funds into the treasury is very low in the form of water rates, or returns to the capital invested on different irrigation projects. "It is often noted that the water cess/water rates collected are so low that they are not sufficient to pay the salaries of the staff and not to speak of reinvestment in the new schemes" (Gulati, **et.al,** 1994; pp.73-75). The mounting costs, frequent revision of project estimates and consequent delays in the completion of irrigation projects have been causing great concern to the government since a long time (GOI, 1993, P.58). Several governments are forced to reconsider their policies toward farmers' payments and for participation in irrigation developmental activity (Small and Car-

ruthers, 1991; P. 28). At this juncture, there is a need for a scientific study of the economics of irrigation water rates, covering the phenomenon of both pre-and post-Independence periods. To conduct such a study taking the entire nation as a unit, is not viable. Hence, the scope of the study is limited so as to facilitate comprehension of as much reality as possible. Consequently, Andhra Pradesh is chosen for a case study. The development of irrigation in pre-Independence period is very significant, especially in the major area of Andhra Pradesh, as a number of projects were constructed by the British Government of the Madras[11]. Hence, the study of their policies on irrigation is highly valuable. There have been no major recent studies about water rates in the state of Andhra Pradesh.

REVIEW OF LITERATURE :

The approaches to irrigation pricing need to be understood in relation to the objectives of a nation's irrigation development programme. Among the various economic considerations of irrigation planning, some primary concerns of the pricing of irrigation water can be identified. Increased national food production, help to the subsistence farmers, national and regional development and generation of increased revenues to the Government are some such considerations.[12] (Small L.E, **et.al.**,1989, P.1). But other considerations such as employment, income and sustainability.are much more important than these objectives,

IRRIGATION PRICING AND DEVELOPMENT :

Increased national food production is an objective underlying irrigation development of many nations. In Bangladesh, a rapid increase in irrigation was seen as a key element in meeting the primary objective of the medium term food production plan, "to ensure food security to the nation by achieving foodgrain self-sufficiency" (Huq, M.1980, P.168). Achievement of self-sufficiency in rice has also been an important element underlying the irrigation development plans of the Philippines and Indonesia. In Malaysia, the government used irrigation as a means of increasing the domestic production for rice consumption in the country (Small, L.E., **et.al.**, 1989, P.1). Just as irrigation development is seen as an important component of the strategy for achieving the self-sufficiency objectives of these nations, the irrigation pricing mechanism must also be seen as consistent with these objectives.

Increasing the production and income of farmers for their subsistence was the chief objective underlying the development of irrigation in India and Pakistan during the late 19th and 20th centuries. Projects which, when judged by a financial productivity criterion, were deemed to be "unproductive," had an important place in the irrigation development programme if they would benefit the nation by reducing famines. Such projects might also have some fiscal advantages to the government in the form of reduced expenditures on famine relief (National Council of Applied Economic Research, 1959 : P.65). The explicit income

distribution objective associated with this policy had clear implications for pricing mechanisms. In particular, it would be inconsistent to use a mechanism requiring the water-users to pay for the full cost of the development and operation of the irrigation system. Investment in "Productive" irrigation works thus had an objective similar to that which governs investment in a profit motivated private sector. This had obvious implications for the types of pricing mechanisms that would be appropriate. The formulation of irrigation water price is likely to be influenced by a large number of variables. Most of them can be conveniently reviewed under the impact of irrigation.

IMPACT OF IRRIGATION

The direct impact of irrigation is chiefly on productivity, employment and environment. Indirect effects and the profits earned on commodities of the projects which are sold locally, profits expected to accrue to all other enterprises between the farmers and the final consumer, from handling, processing and marketing and, profits of all enterprises from supplying goods and services for the increased farm purchases for family living and production expenses.

PRODUCTIVITY

Irrigation has the potential to increase agricultural output. Whether or not the individual cultivator benefits from any such increase depends mostly on the style of irrigation management. Cultivators may be tenants, land owners or work as land-

less labourers. They may get fixed wages or share in total profits. Comparison of productivity between irrigated and unirrigated lands in a given are showed that irrigated lands had a larger increase in productivity (Vaidhyanathan A, 1987, P.510). For example, in the Dantiwada project of Gujarat, the output per hectare of gross crop area is estimated higher in irrigated lands, produce nearly twice the per hectare of gross crop are compared to unirrigated lands. There is ample evidence to show that "individual crop yields are considerably higher under irrigated than under rain fed conditions and that irrigated areas grew high value crops which can not be raised at all under rainfed conditions" (Ranade, 1980, pp.85-114). It has also been shown that differences in the progress of output per hectare as well as crop intensity across space are significantly and positively associated with the irrigation ratio. The positive correlation between growth of irrigation and growth of agricultural production, mainly crop production. Public investment in irrigation is seen to be a significant determinant of agricultural growth (Rao, S.K, 1971, pp.1333-53). The study found that relative stagnation in agricultural growth rates during the early sixties was due to declining public investment, while higher growth rates during the "Green Revolution" was found mainly related to a high growth in public investment.

Nadkarni used the production function approach to analyse the effects at different levels and types of irrigation on output, treating irrigation as one of the explanatory variables. The micro survey show that the productivity impact of irrigation

varies between projects and across regions. The survey in Karnataka found that different types of irrigation showed variation in productivity : the areas irrigated by wells have higher cropping intensity and higher yield than tank-fed areas (Nadkarni, et.al., 1979: pp.50-70). This study reported even larger differences ranging from five-fold to twenty-fold of higher yields, and indicates the volume of output per unit of gross sown area and net sown area is significantly higher in the command areas than in the non-cmmand areas.

Estimates regarding the impact of irrigation, source-wise, on yields, the stability of yields and their regional variations were prepared by Dhawan (1983 : pp.109-16). The direct estimates of productivity differentials between irrigated and unirrigated lands are widened. The cropping pattern explains the major part of the differential rather than differences in yield and also notices important inter-regional differences. Dhawan also found that the productivity differentials between irrigated and unirrigated lands were wider in the low rainfall regions than in the high rainfall regions. High rainfall regions are higher productivity than low rainfall regions.

While the benefits of irrigation are widely recognised, their very nature, stemming from simultaneous changes in technology, input use, resource allocation and behaviour makes them very difficult to quantify and attribute to any one factor such as irrigation. The study by Abbie quantified somehow the benefits from irrigated and unirrigated areas and there are more benefits

much more in irrigated areas. (Leslie, Abbie, et.al., 1982, P.14).

Thus, the investment in irrigation influenced the conditions of production, not only through its technological impact, but through the shaping of the process of development, with differential consequences on the economic position of different classes. Irrigation improved the relative economic position of the users and generated a dynamics of growth and productivity.

EMPLOYMENT AND INCOME:

The use of irrigation facility increases employment opportunities in primary sector in more than one ways. In the first instance, irrigation operation itself needs labour. And increased employment depends on the number of waterings applied to the crops and the actual area covered under different crops. Secondly, irrigation facilitates had increased the use of strategic inputs like fertilizers, insecticides and pesticides which needed labour use at the farm level. Thirdly, assured water supply diverts cropping pattern of a region from inferior crops to more remunerative crops which raise the employment potential on account of increased labour intensity of such crops. Empirical studies confirmed that reliable and adequate irrigation directly raised the volume of employment. Some studies revealed that the volume of employment was more in irrigated lands than those with rain- fed conditions. It is reported to have been 61% of employment increased on the Dantiwada canal irrigation project

in Gujarat (Patel and Patel, 1984 : P.538) and more than 100% of employment increased under the Kakatiya canal of Sriramsagar project in Andhra Pradesh (Adinarayana, S.1984 : P.543), and 135% of employment increased in a village under the Damodar valley canals in West Bengal (Ghosh, M.G.1984 : P.549). Another study with empirical evidence from 45 micro studies, (25 of them from India) found that, with few exceptions, they confirmed the positive relationship between irrigation and employment (Silliman and Lenton, 1985 : P.16). For small and marginal farmers, irrigation means increased productive work spread throughout the year. For landless labourers, irrigation means work available on most days of the year, especially where there are a second and third crops. A comparison of an irrigated village with a largely unirrigated village in West Bengal showed how sharp the contrast could be for labourers. In the irrigated area there was virtually no dead season and also that a large number of migrant labourers could find work in the peak seasons (Ghosh, M.G., 1984, P.549). Wages also were high when there was a sharp peak in labour demand. With a continuous demand for labour throughout the year resulting from irrigation, employers took on to semi-permanent or permanent labour (Wood, G. 1985 : P.24). Thus, development of irrigation helps to stimulate the growth of non-farm employment of a region. The activities like rice milling, cotton ginning, repairing and maintenance activities of improved agricultural implements and other activities of agricultural sector generate additional employment opportunities in the economy.

ENVIRONMENT

Irrigation projects affect the environment. Some have adverse effects on it, while others have beneficial effects. In India, the projects like Ujjine and Jayakwadi on both of which more than Rs.500 crore each have already been spent are classic examples to show how projects are planned ignoring basic socio-economic and environmental considerations (Desards, 1994, p.181). The deep black soils in planned command areas of both projects are the most ill-drained soils. And as the drainage components are conspicuously missing in the project design itself, even with a few trail irrigation rotations the soil is getting soiled on account of salinity and alkalinity. Environmental damage caused by construction of reservoirs submerges valuable forests and displaces people (Vaidyanathan, 1987, p.525). But the study also finds that the reserviors helped to increase output of agricultural produce including the basic foodstuffs. Though there are benefits from the irrigation facilities, they are immediate and short-run. However, in the long-run, it would lead to the adverse effects on environment.

IRRIGATION AND INVESTMENT ALLOCATION

Increasing the government revenues was one of the objectives of irrigation development in India. This has been emphasized by a number of studies. The donor agencies such as the World Bank and other financial agencies and the India herself had invested crores of rupees in the past four decades in irrigation and are planning to invest crores of rupees more in the coming years.

But research on the socio-economic and institutional issues involved in the development and distribution of investment on irrigation through public investment programme have started receiving serious attention from many of the studies only recently (N.C.A.E.R, 1959, P.65; Prasad and Rao, 1985, P.17). The rise in the quantum of investment in irrigation sector induced several additional economic activities in the economy. These in turn, enhanced production, employment opportunities, and trade.

The cost escalation and the delay in the completion of the major irrigation and multi-purpose projects under various heads, such as rise in prices, inadequate investigation, inadequate provision, change in the scope and design of additional requirements, acquisition of lands, rehabilitation measures, paucity of funds, poor performance of equipment, and management of water resources projects, not only pushed up the cost of the project but also resulted in postponement of the completion of the project owing to the inability of the states to provide additional funds to commensurate with the rise in costs (GOI, 1980 : P.24). In such a situation, where the State is investing enormous amounts of public money, largely borrowed, without recouping any part of it, increases the burden on the already severely strained budget and is bound, in course of time, to affect adversely the ability of the State to maintain or to continue expanding and improving irrigation. This gives room for enhancing the recovery costs through pricing of irrigation mechanism.

WATER RATES :

The effects of financing policies depend mainly on the organization of responsibilities for the four processes of allocating resources to irrigation, using these resources to implement irrigation services, obtaining resources from irrigation beneficiaries, and controlling the resources obtained from the beneficiaries.

Irrigation policy of colonial administration between 1860-1900, was a revenue oriented policy. Irrigation land in the Madras Presidency was assessed in a consolidated payment which represented in one sum the assessment of land revenue and the charge for its irrigation (GOI, 1865, pp.131-133). Further, the colonial government left the less endowed regions where the rate of return was low, to the private companies and kept the better endowed regions, where the profits were much higher, to itself (Ratna Reddy, 1990, pp.1047-54). The colonial rulers discouraged farmers in maintaining irrigation systems whenever there was a surplus revenue to be realised.

Water rates in the colonial state under the Godavari, the Krishna and the Pennar, it had noted some formalities and policies of the native rulers on irrigation before the British advent which was marked primarily by the non-commercial and general welfare considerations (Atchi Reddy, 1992; P.1-14). The native rulers used to help the owners of the irrigation sources with finances that were not expected to be directly returned in

any form and at any time. There was an apparent change in this policy during the colonial British Government as the rate of the expected profits increased their revenues. It was due to considerations of commercialization. The initial stages of this change gave rise to a number of water conflicts and tensions. The main reasons, were the increased yields after the construction of **anicuts** and control of floods particularly in the command areas of these **anicuts**.

GROUND WATER MARKETS:

The phenomenon of market for ground water has been widely documented in the context of both Indian and Bangladesh agriculture. These available literature pertains to the markets in areas where availability of ground water is relatively abundant and where the rates for water are competitive. During the first round village level survey in the Vaigai basin, 27 villages were surveyed, and rate was fixed for water sale in this basin for wet and dry lands separately. A few well-owners depended on their wells and who have surplus water to sell benefit by this (Shah and Raju, 1988 ; P.A.23-28). In fact, many well owners who had shortage of water purchased it in this region. Water charges are collected in cash and they do not vary in respect of wet and dry lands, but one finds variation in water charges from village to village. The water rates vary depending upon the quality of water and the type of energy used. Poor quality water, in general, is charged low. If a diesel pump is used for lifting water, rates are high, irrespective of the quality of water (Janaka Rajan, 1993, pp.65-67). Another study is that relative signifi-

cance of various factors influencing the ground water purchasing decisions of the farmers in the five Indo-Gangetic states, viz., Bihar, Haryana, Punjab, Uttar Pradesh and West Bengal was studied by Maria Seleth. The farmer buying ground water depends upon his attributes like farm-size in acres, number of farm fragments, soil fertility, percentage of his farm area under canal irrigation, water payment (per acre) irrigation expressed in rupees, timeliness of rain, adequacy of rain, fertilizer applied in kg/acre, and the adoption of high yielding crop varieties. The study concluded that the failure of climate i.e delayed rainfall has been the major factor contributing to the decision of farmers to buy ground water in all the five states (Maira Seleth, 1991; P.349-54). The structure and performance of water markets in North Coastal Andhra Pradesh were studied by Raju and Rao. According to them, all the selling firms were medium farmers and all the buyers were small farmers, because small farmers were not in a position to afford to introduce the diesel pump systems. (Raju and Rao, 1991, p.376). This kind of water market system is in vogue in North Coastal Andhra Pradesh.

Pricing of irrigation, with emphasis on cost of producing unit quantity of water at the water point and charging economic water rates was studied by S.P.Sangal (Sangal S.P, 1991; P.2645-51). This study stated that in two states namely Gujarat and Maharastra, water rates of these minor irrigation projects had fully covered the operation and maintenance charges, yearly component of loan along with its interest after accounting for subsidy for the assets created.

ASSESSMENT OF IRRIGATION REVENUES:

A distinction may be drawn between situations of full or partial financial autonomy and those of financial dependence. With financial autonomy, an irrigation agency has at least partial responsibility for allocating, implementation, fund collection and controlling of finances of irrigation (Nickum, 1976; pp.169-86; Bergman, 1984; pp.9-13; Bottrall, 1983; pp.102-13; and Khan, 1981; pp.55-66). These studies on financial obligations revealed that, financial autonomy and control over the resources obtained from the water ways, and thereby over the allocation of all or a major portion of the resources devoted to irrigation operation and maintenance.

Another study regarding financial autonomy may involve either decentralized implementing agencies or a centralized irrigation agency. With financial dependence, an irrigation agency has no control over any funds collected from the water users, and is thus dependent on resources allocated to it through the general government budgetary process. Decentralized financial autonomy is found in a number of countries where control of irrigation operations is vested in local irrigation authority in the USA, Mexico and China, companies in France, land improvement associations in Korea, and irrigation associations or co-operatives in Taiwan and Greece (ADB and IIMI, 1986; P.8). They concluded that one of the potential advantages of decentralized financial autonomy is that it may create financial accountability linkages between the managers of irrigation projects and the

water users. The centralized irrigation agencies may also be financially autonomous, although this appears to be relatively uncommon. In the Philippines, where semi-governmental corporation, viz; the National Irrigation Administration, is responsible for the construction and operation of national irrigation systems throughout the country. Further, they observed that a common alternative financial arrangement is that of financial dependence, whereby a government line agency responsible for operating irrigation projects depends solely or primarily on government budgetary procedures for its revenues. This approach prevails in a number of countries including Nepal, Indonesia, India, Pakistan, Bangladesh and Srilanka. In these countries, the amount of water charges collected from farmers have little or no relationship to the amounts spent on the operation and maintenance of the irrigation systems (ADB and IIMI, 1986; P.9). That means, these revenues in the name of water charges are not sufficient to meet the expenses of maintaining the systems.

Assessment of financial obligations is usually based on the cost benefit principle. When the cost approach is used, it is common for the government to provide subsidies that cover some specified portion of the irrigation costs. Typically, the subsidy involves a portion of the capital costs, (either for initial construction or for major upgrading or rehabilitation), but no portion of the operation and maintenance costs. The cost principle is some times modified to accommodate considerations related to the amount of benefits received. Considerations of ability to pay appear to have been incorporated into policies on water

charges in the U.S.A, Taiwan and Korea, where the government has set a maximum amount which farmers can be charged for water by the irrigation associations. In some cases, if the costs of the irrigation association cannot be met by these maximum charges, special subsidies may be provided by the government. Some studies observed that there were a number of problems connected with the cost principle (Kimura, 1977 : pp.248-66; Bottrall, 1983; pp.102-13; Small and Carruthers, 1991: pp.39-71; Young, 1986 : pp.151-175; Nickum, 1976 : pp.169-86; and Khan 1981 : pp.55-66). It has been argued that, because of corruption, inefficiency and other leakages, officially reported cost figures for irrigation, in several countries may be as much as double the appropriate or real level that user should be expected to repay.

The benefit principle is consistent with financing mechanisms that place some financial obligations on indirect beneficiaries of irrigation. In India, it is reported that betterment levies had been tried in various states, but without much success. The Planning Commission studied the pricing of irrigation water under which the Commission reviewed different procedures for the cost-benefit analysis of irrigation projects (GOI, 1992; pp.58-91). The water charges should explicitly be the function of the volume of water used and the season of use. The amount paid by the users of irrigation water should be linked to the quantity used and the quality of service received. A shift to volumetric pricing which measures water in quantity delivered would remove the need for fixing crop-specific rates.

Finally, it is not possible for a centralized agency to efficiently administer the use of water at thousands of points across a large irrigation system without the help of user farmers, without building up strong and effective farmer's organizations which can take up the responsibility of receiving bulk supplies of water from the irrigation department and distributing the water among the member farmers (Ashok Gulati et. al., 1994, PP.A-72-79) . This may bring about a substantial reduction in the costs and responsibility of the government agency.

The above review assumes that after irrigation, land holding remain unchanged, large farmers remain large farmers, small remain small and the landless remain landless. Although irrigated land ceilings in India are lower than the non-irrigated, actually not much land was acquired in the land reforms under canal irrigation. The relation between costs and benefits has a direct bearing on the economic viability of irrigation as well as the rational allocation of irrigation outlay across regions and recovery of revenue from these benefits.

GAPS IN THE KNOWLEDGE OF IRRIGATION RATES :

The studies discussed did not give much importance to water rates. Some studies gave importance to the benefits from irrigation, i.e., improving production and productivity levels (Vaidyanathan, Dhawan, Nadkarni etc.,), while others stressed on the investment allocation and financial obligations, i.e., allocation

and financial autonomy of irrigation systems (GOI, ADB and IIMI, Nickum, Kimura and Khan etc).

Most of the recent studies dealt with the ground water markets (Shah and Raju, Janakarjan, Raju and Rao etc.). They did not analyse at length the canal irrigation and water rates. Some studies touched on minor irrigation water rates especially water rates in British India (Subbalakshmi and Subhramanyam Chetti). Irrigation development and water rates under canals are only noted by them. The studies reviewed did not give much importance to development of canal irrigation. Economic analysis of irrigation pricing hardly attracted the attention of researchers in recent times. No study clearly mentioned the setting and collection of water fees. There is no detailed study on any aspect of irrigation pricing in Andhra Pradesh.

The reason is that the large-scale irrigation system is a high cost proposition. The exploitable capacity of irrigation potential of large-scale projects covering nearly 58.5 million hectares of crop area in India is more than that of minor irrigation works, standing at 17.4 million hectares. Large amounts are spent on major and medium irrigation projects. This capital outlay is entirely on public sector account, mostly spent through irrigation departments of the state governments. The corresponding public sector outlay on minor surface irrigation development is obviously less and not known precisely. Thus, bulk of the public sector outlay allocated on surface irrigation works was

for the development of major and medium irrigation projects and this has been enhanced in all the Plans since 1951.

OBJECTIVE AND HYPOTHESIS :

The objective of the study is to analyse the trends in the water rates in Andhra Pradesh from 1865 to 1990. Different methods of price fixation of irrigation water of the major and medium irrigation sources are studied to project the price fixation of irrigation systems, and for the future development of irrigation.

The hypothesis of the study is that the share of water rates has been steadily decreasing as a percentage of the total crop output of the area irrigated.

METHODOLOGY:

The present study investigates the economic effects of water rates. The purpose is to capture all effects - direct and indirect. Primary and secondary sources of data dealing with irrigation in general and water rates in particular, are collected. Chief explanatory variables involved are productivity of crops, prices of crops, cost of cultivation, cost of providing water, and cost of maintenance of irrigation. There are other and minor variables whose effects are brought into focus whenever possible through the medium of the above variables.

The cost recovery issue is concerned with the level and structure of the prices to be charged for the benefits from a

project so as to maximize its net economic benefits to the economy. The scope for efficiency of pricing irrigation water is limited, especially those serving numerous small plots of land metered sale of water is costly to implement and administer and is rarely practised in developing countries. In the absence of volumetric pricing, where metering is too difficult to allow pricing - as in major and medium schemes, the most suitable means of recovery is a production benefit tax. Crop-wise or area based rates, which are an attempt to tailor such a tax to a particular service, need to support heavy rates of recovery. Otherwise, they may induce distortions to cropping patterns and water use. Gross value of output per acre/ hectare base is suitable for measure with fixation of water rates.

However, there are no uniform water-rates in different areas. Hence the difficulty of fixing the water rate for a general frame work of method. For the analysis, projects from three different regions of Andhra Pradesh are chosen. There are different modes of rates in different projects. In this way the study attempts to analyze a comprehensive and much wider impact of economics of water rates on irrigation.

Comparative approach is adopted in this study. It begins with the adoption of water rates by the British Government in 1865. The study noted the changes adopted by the British government in the later years. It takes into account the water rates imposed by the Indian government after Independence.

AREA OF THE STUDY:

The present study concentrates on Andhra Pradesh as there was no significant study which highlighted water rates of irrigation. The area of study consists of three different geographical entities, viz., Andhra, Rayalaseema and Telangana. While selecting the area of study the advantages of the case study and the availability of data were taken into consideration. Since the three regions consisted of numerous large and small irrigation projects, Andhra Pradesh is selected as the area of study. Another reason is the existence of different types of wet areas and a substantial percentage of area under irrigation. However, all the wet areas of the three regions do not form the part of study. For a deeper analysis of the impact of water rates on irrigation, selective projects namely, Godavari, Krishna, and Nizamsagar **anicuts** are chosen.

PERIOD OF STUDY:

The study begins with the year 1865 for the reason that the introduction of separate water rates on irrigation by the British Government were proposed in that year. Prior to 1865, Andhra region witnessed the completion of Godavari, Krishna and Pennar **anicuts**. It was on these projects, the British Government for the first time applied separate the water rates on irrigation in Andhra. This process of application of water rates by the British continued till the end of their rule. After Independence, a similar policy was adopted by Andhra Pradesh government, though

there is a clear distinction between the two. Thus, the study continues up to 1990, when the Government of Andhra Pradesh introduced an Act regarding water rates whose impact is altogether a different phenomenon[13].

SOURCES OF DATA:

The sources are numerous and varied. They included Government reports and records. Caution has been taken particularly while referring to the British Government records. The colonial attitude in general was to justify the policies of the British Government. There is an Act on the irrigation cess / water rate in Madras Presidency called Madras Irrigation Cess Act of 1865[14]. It noted about the existence of various kinds of irrigation systems and methods of levying water rate in different regions and under different projects of the Madras Presidency. The Board's consultations and the precedings have a wealth of information regarding the individual projects and water rates in different regions especially. Apart from these primary sources, numerous secondary sources like books and articles are consulted. Annual data on irrigation charges payable to the government in lieu of water supplied to the farmers from the government owned canals and other means of irrigation are collected from the Board of Revenue precedings of the Madras Presidency, Central Water Commission Reports, Ministry of Irrigation and power and Agriculture Reports are others.

ORGANISATION OF THE STUDY:

The work is presented in the sequence of chapters. The first chapter is Introduction which discusses the problem, review of literature, area and period of study, objective hypothesis and methodology of the study.

The economic theory of irrigation pricing, the role of government in irrigation development and the available different pricing principles are discussed in chapter Two. In the Third chapter, the economics of water resources of major as well as medium irrigation projects in India in general and Andhra Pradesh in particular, the uses and users of water resources and their consequences, are examined. The capital cost, operation and maintenance cost of major and medium irrigation schemes and cost recovery are dealt with in chapter Four. The Fifth chapter deals with the critical examination of irrigation rates from the British rule till the present times.

In chapter Six, the benefits of irrigation are noted and the productivity, prices and water rates are analysed. Chapter Seven discusses the subsidisation in irrigation sector.

Chapter Eight, i.e., the concluding chapter lays emphasis on the role of water rates as a mechanism to raise returns for further expansion of irrigation facilities.

NOTES :

1. The pattern of agricultural growth during the nineties represents a shift in the cropping pattern and the spatial distribution of crops in response to the emerging resource and input constraints which may reflect improved allocative efficiency and interplay of improved management techniques in production. The increased productivity of rice could be explained to some extent by the area shift from high irrigation and input intensive north-western states (Punjab and Haryana) to more heavy rainfall areas of West Bengal, Bihar and Orissa having less irrigation facilities but abundant cheap labour. Rice being both a water intensive and labour intensive crop is perhaps better suited for the eastern states with a natural comparative advantage for growing this crop. Given the heavy concentration of poverty and agricultural boundaries, expansion of rice cultivation in these states as well as in other parts of India would have provided additional employment opportunities minimised large scale `uneconomical' migration of labour from these states to the western states of India (Vinita Kumar, 1997, pp.212-214).

The growth of agriculture, especially of the oil seeds sector, at the expense of coarse cereals resulting in cheap availability of edible oils vis-a-vis coarse cereals is expected to have brought about shifts in the consumption pattern of these commodities. Edible oils are generally considered superior in terms of nutrition when compared to coarse cereals. Whereas vegatable oils are known to be rich in calories derived from fat,

coarse cereals have an abundance of minerals and vitamins in addition to protein and calories (Vinita Kumar, 1997, P.216).

According to the population census (1991), agriculture continued to remain the most important sector in the rural economy employing 110.7 million persons as cultivators and 74.6 million persons as agricultural labourers out of a total of 285.9 million workers in its agriculture (Census of India, 1991, P.18).

2. A task force was set up by the Planning Commission in 1977 to estimate the minimum needs. Based on the age-sex-occupational characteristics of the population, the task force arrived at a norm of 2435 calories for rural areas and 2995 calories for urban areas. Using appropriate conversion factors, the calorie content of consumption baskets corresponding to various per-capita expenditure classes was worked out (Government of India, 1979, pp.1-31).

3. A new strategy for agriculture for the Fourth Five Year Plan was outlined in 1965 with the following objectives : First, to apply scientific techniques and knowledge of agricultural production at all stages, particularly in the fields, Second, to select a few areas with assured rainfall and irrigation for concentrated application of a package of inputs based on improved varieties of seed responsive to heavy doses of fertilisers, and on other modern inputs. And third, to achieve higher production of subsidiary foods both through intensive production programmes and

overall development (Government of India, 1965, and Das Gupta, B., 1980, pp.42-44).

4. According to the Report of the Expert Group on Cropping Pattern, with the compound growth rate of total foodgrains 1967-68 to 1984-85 at 2.68, the projected foodgrains for the years 1989-90 were 162 million tones, 1994-95 were 185.91 million tones and for 1999-2000 were 212.19 million tones respectively. And projected demand for foodgrains during year 1999-2000 was 221.00 million tones (Government of India, 1988, pp.1-17)

5. With an annual total expenditure of Rs.1558 billion for a population of 797 million, per capita monthly expenditure comes to Rs.163 in 1986-87. The rural-urban difference in per capita expenditure was fairly large. The rural areas had a per capita expenditure of Rs.141 per month with two-thirds of it devoted to food, whereas urban areas had Rs.226 per month with slightly more than one half devoted to food. Though, the share of food in total expenditure was low, urban areas had a higher per capita expenditure of 39% on food because of their higher level of per capita expenditure (Radhakrishna R and C. Ravi, 1992, pp.2-3).

6. The Government adopted a multi-prongsed strategy to effect income distribution in favour of the poor. The policies and programmes for indirect and direct transfer of income to the poor which encompass input subsidies in agriculture, food subsidy through the public distribution system and self-employment and

wage employment programmes for the rural poor. Whereas the first-two interventions only had an indirect bearing on poverty through availability of foodgrains at low prices (Vinita Kumar, 1997, Op.cit., pp.164-205).

7. The progress of Indian agriculture since the introduction of economic planning in the country is substantial. There has been growth in the production of all the crops, though at different rates. However, this growth has not been smooth. It has become increasingly unstable. At least two factors seem to be contributing to increased fluctuations in crop output. Firstly, crop output, particularly of foodgrains, is sensitive to variations in rainfall. Secondly, changes in the prices of inputs like fertilisers relative to those of crops would also include the demand for inputs resulting in variation in output (Hanumantha Rao, CH., **et.al.,**, 1988, P.15).

8. India lost rich rice growing areas to Burmah in 1937 and the large Sukkur damage to Pakistan in 1947.

9 Rationalisation/restructuring of water rates is envisaged, in view of the urgent need for upward revisions so as to bridge the widening gap between receipts and expenses. Fixation of water rates at present in under the purview of the State governments. Some states have already undertaken works relating to improvement of irrigation systems and farmers turnover with a view to recover full operation and maintenance costs in a phased manner (U.N.O., 1996, p.17).

10. There is a variety of political interests and pressures affecting the practical establishment and implementation of financial reform of irrigation institutions. Inevitably, the issues that arise will include the political viability of any scheme for irrigation fees; the genuine political problem of charging low income farmers anything at all, even if product prices are increased ; the opposition to reform of officials who benefit from the opportunities for corruption, created by the economic rents that occur in subsidised irrigation and coping with the genuine social and cultural impediments to change when traditional values are in conflict with modern methods of financing (Small, L.E, and Ian Carruthers, 1991, P.203).

11. The Madras Presidency occupied the southern portions of the Peninsula from latitude $20^{o}18'$ on the eastern coast and latitude 14^{o} on the western coast to Cape Comorin in latitude $8^{o}4'$; the longitude ranges from $74^{o}9'$ to $85^{o}15'$. The extreme linear length of the Presidency, from North-East to South-West, is about 950 miles, its extreme linear breadth is about 450 miles. The coast line on the east commences North at the confines of the large salt lagoon called the Chilka lake in the Bengal district of Cuttack, and gives a boundary successively to the Ganjan, Vizagpatnam, Godavary, Kistna, Nellore, Madras, Chingleput, South Arcot, Tanjore, Madhura, and Tinnevelly districts, and a small portion of the Travancore state. This makes about 1,250 miles of coast washed by the Bay of Bengal, Palk strait, and the Gult of Mannar. The coast-line on the West commences North at the vil-

lage of Shiroor a few miles south of Bhatcal near the Honore estuary, being the boundary between the Bombay district of North Canara and the Madras district of South Canara, and gives a boundary successively to the South Canara and Malabar districts and the Cochin and Travancore States. This makes a coast line of about 450 miles washed by the Arabian Sea. On every side but the North, the Presidency is washed by the open sea. The irregular northern boundary has been formed by accidents of history.

On the extreme North-East is the Bengal Province of Orissa; next come the highlands of the Central Provinces; then across the greater part of the Peninsula the Dominions of the Nizam of Hyderabad, separated from the Madras by the Kistna river and its tributary the Toongabhadra, lastly, on the north-west by west, the districts of Dharwar and North Canara in the Bombay Presidency. This description leaves out of a account the Mysore and Coorg territories, which geographically speaking as much a portion of the Presidency as do the tributary states of Travancore and Cochin on the South.

From a physical point of view, the Presidency may be roughly divided into three portions, the long and broad Eastern Coast, the shorter and narrower Western Coast, and the high table land in the interior. These divisions are determined by the two great mountain ranges of the Eastern and Western Ghauts which give the key to the configuration of all Southern India. The Eastern Ghauts, which lie entirely within this Presidency, a continuation of the hill system of Chotanagpur. They run in a South-Westerly

direction almost through the entire length of Madras, until they lose themselves in the Neilgherries, and there join with the Western range. Their line is pierced by the Godavary, the Kistna, and the Cauvery rivers, as well as by minor streams, so that they do not perform the part of a watershed. The Western Ghauts on the other hand, which stretch south wards continuously along the share of the Indian ocean from the north of Bombay, satisfy all the characteristics of a mountain range. The peculiar physical geography of the Peninsula with a large mountain chain running from North to South along its Western boundary, is of importance in regard to climate and the productions of the various portions of the country. The Western hills have the effect of arresting the lower strata of rain clouds brought up from the Indian ocean by the periodical winds of the South-West monsoon, and of causing excessive rain precipitation on the narrow strip of coast-line on the Western side of the Peninsula. To the physical barriers of the Western Ghauts must be attributed not only the vast differences of climate, but also those of the nature of the productions, in the Eastern and Western divisions of the Peninsula. In the former division the uncertainty and capricious character of the rainfall has taught the cultivators of the soil the necessity of making provision for the storage of water for irrigation purposes, and in memorable tanks of reservoirs scattered throughout the country. On the Western side of the mountains, however, the necessity for such works has never arisen. The chief staples of the Presidency are rice ; **cholam, cumboo, raggy, and varagoo**, gingerly; chilies, tobacco, sugarcane and cotton (Maclean, C.D., 1987, pp.1-20).

12. According to Small, L.E., M.S. Adriano, E.D.Martin, R.Bhatia, Y.K. Shim, and P.Pradhan, have been set objectives include stabilisation of production, food self-sufficiency, famine protection and land settlement **(International Irrigation Management Institute,** 1989, P.1).

13. In the Andhra Pradesh Water Tax Act, 11 of 1988 the government have rationalized the levy and collection of water rates in the state, by introducing uniform water rates on all lands by treating all lands whether classified as wet or dry in the Revenue records, as dry. In levying uniform water rates all major and medium irrigation projects are classified in the Act under category - I and other Government Irrigation Sources which supply water for a period of (5) months and above are classified under category - II and to collect the water rates from 1.7.1986 (Government of Andhra Pradesh, Order No.11, Revenue Department, dt.24.08.1989).

14. N0.8 of 1865. A bill to enable the Government to levy a separate cess for the use of water supplied for irrigation purposes in certain cases. Whereas in several districts of the Madras Presidency, large expenditure out of Government funds has been and is still being made in the construction and improvement of works of Irrigation and Drainage, to the great advantage of the country and of proprietors and tenants of land, and whereas

it is right and proper that a fit return should. in all cases alike, be made to Government on account of the increased profits derivable from lands irrigated by such works.

It was enacted as follows :

"Whenever water is supplied or used for purposes of irrigation from any river, stream, channel, tank, or belonging to, or constructed by Government, it shall be lawful for the Government to levy, at pleasure, on the land so irrigated, a separate cess for the use of the water, which cess shall be additional to any land assessment that may be leviable on the said land as unirrigated or punjah and the government may prescribe the rules under which, and the rates at which such water cess as aforesaid shall be levied, and alter or amend the same from time to time" (Government of Madras, 1865, Order No.986, pp.361-64).

CHAPTER - II

ECONOMICS OF WATER RATES : SOME CONCEPTS

Introduction:

Efficient management of water resources requires the recognition of the fact that the overall water resources are linked to the national economy. Equally important is the understanding of how alternative economic policy instruments influence water use across different economic sectors as well as between local, regional and national levels and among households, farms and firms. Macro-economic policies and sectoral policies that are not aimed specifically at the water use may have a strategic impact on resource allocation and aggregate demand in the economy. A country's overall development strategy, use of macro-economic and trade policies and fiscal policy, government expenditure on irrigation, flood control and building of dams affect the demand and investment in water related activities directly and indirectly (**F.A.O, 1995, P.256**). Therefore, the important economic attributes of water in use need to be analysed. Further, these economic attributes of water resource projects determine the charges for project outputs.

There is a limitation in reconciling water as purely economic good with the traditional idea of water as a basic necessity

for humanity. Like fresh air, water was once considered a free good, but now it is becoming scarce. Scarcity is one of the most important issues in considering the various socio-economic trade-offs in allocating water among different uses. Developing effective water use policies is difficult for a number of reasons. They include physical and administrative issues too. Water has got unique physical properties, complex economic characteristics and important cultural features that distinguish it from all other resources. Management of water resources is administratively complicated because it involves legal, environmental, technical, economic, and political considerations. In most societies, immediate political considerations dominate decisions on water resource use[1].

Economic Attributes of Water in use

Economic benefits provided by water may be conveniently put under four heads. Benefits are from commodities, waste assimilation, aesthetic and recreational, fish and wild life habitats (F.A.O, 1995, P. 259). Individuals derive commodity benefits from water by using it for drinking, cooking and sanitation. Farms, business and industries obtain commodity benefits by using water in productive activities. These commodity benefits represent private good uses of water which are rivals in consumption. One person's or industry's water use precludes or prevents its use by others. Government policies and regulations that concentrate on improving market access and competition are important means for improving the productive and allocative efficiency of the commodity uses of water.

The second and increasingly important economic benefit of water is waste disposal. Water bodies have a significant but ultimately limited assimilative capacity to process, dilute and carry away wastes. The surface water flows into large channels, ponds, lakes and rivers while some of it carries waste disposal into the sea. Thirdly, Recreation and aesthetic benefits and fish and wildlife habitats were once regarded as luxury goods outside the concern of governments[2]. Waste assimilation and recreational and aesthetic values are closer to being public goods than private goods (F.A.O, 1995, P. 259). Public goods are non-rivals in consumption, - one person's use does not preclude use by others[3]. The quality of water from different sources varies widely. Precipitation absorbs gases from the atmosphere and removes particles from the air. When the precipitation strikes the ground it becomes surface water run-off or enters the ground.

However, along with these benefits, many pressing irrigation issues reflect the various economic, social and political influences affecting economic conditions. At times, irrigation related problems are the result of a distorted macro-economy, which, despite providing operating subsidies, renders farming unprofitable and results in repeated under-investments on farms over long periods[4]. The overall performance of many irrigation projects is disappointing, including cost and time overruns, poor management, the non-realization of full cost recovery and planned benefits, adverse environmental and health impacts, and the

exacerbation of inequalities in the existing social and economic distribution of assets among farmers.

Economic Organization and Water Allocation :

Most countries rely on a mix of market policies and direct government interventions to manage water resources. Each system has its own advantages and disadvantages. The term "market system" is used by economists in two senses. It may refer, in one sense, to an actual functioning system, meaning the set of institutional and cultural arrangements that serves to allocate resources through the price mechanism (Young R.A., 1986, P. 152). In another sense,, it refer to an intellectual idealisation, has been studied to determine how apparently unrelated sets of activities achieve economic order, such that goods and services are provided to consumers at the place, time, and form desired, and capital, labour, and natural resources are organized through the productive system to provide these requirements.

Any market system has to provide answers to some questions. What goods and services are to be produced ? What technologies are used in producing them ? Who is benefiting from the use of the products ? (Hey, J.D, (eds), 1993, P.264.). The answers for these questions, are based on the premise that the personal wants of individuals should decide the employment of resources in production, distribution, and exchange and the individuals themselves are the best judges of their own wants.

A competitive market system has many producers and consumers who are well informed, motivated by individual self-interest, and individually owned and controlled resources can be shown to have certain desirable properties (Young, R.A., 1986, P.153). One such desirable attribute is that the system would produce the maximum valued bundles of goods and services to consumers, given the endowments of resources such as the available technology level, the tastes and preferences of consumers depending on their income. Individual producers and consumers, acting within their own self-interest will, in accordance with Adam Smith's "invisible hand", arrive at an allocation of resources which can not be improves upon. Producers, encouraged by prospective profit, buy inputs as cheaply as possible, combine them in the most efficient form, and produce those things which have the highest value relative to cost (Adam smith, 1925, pp.419-421). Consumer's tastes and preferences influence their expenditure patterns, thereby encouraging firm to produce the commodities most desired, and producers allocate resources in the direction of greatest profits. The firms most successful in the process of producing desired goods most efficiently are rewarded by profit, and the unsuccessful are eliminated, so production occurs at the least cost.

The second desirable property of the competitive market system is its ability to accommodate change in the conditions of production and patterns of consumption. New knowledge and technology are rapidly reflected in the prices which producers are

willing to accept for their products. On the consumer side, changes in income and preferences soon show up in the expenditure patterns. Hence, a market system yields, maximum satisfaction in not only a static, but in a dynamic context (Young, R.A., 1986 P. 153). The actual market system may not always meet the precise preconditions of the competition. The principal problems arise with public or collective goods which are non-rival in consumption, external or spillover costs and un-compensated side effects, such as environmental degradation, pollution and economics of large size. Mixed capitalistic systems are based on the presumption that for most goods and services, the allocation resulting from market processes sufficiently approximates the competitive market system. Where this is not the case, regulatory processes or public production are provided to allocate resources[5].

Obstacles to Market Allocation of Water :

Competitive markets in water, desirable from a conceptual point of view, are not yet common anywhere in the world as a means to a more productive use of resources. Several reasons might explain the relative lack of water markets. These may be physical, economic and conflicting social values (Young, R.A; 1986; P. 154). The physical obstacle arises due to the nature of water and how it is used in production and consumption activities. The economic problem arises from the fact that, until recently, water has been in relatively plentiful supply, and the conflicting obstacle caused in that material well-being is not

the only yardstick used by society to measure success in water allocation.

Physical barriers in water stem from its mobile, and flowing nature, which is seldom fully `used' by the consumer, and which has potential for absorbing and carrying pollutants (Barrow, C., 1987, pp.209-210). On form water losses are high. The amount of water which reaches a plot of land is usually less than 70% of that received at the turnout. Commonly it is a mere 20% or less. The ratio of the amount of water applied to the crop to the amount of water delivered at the turnout, well or other point of supply is turned the farm conduity efficiency. Still more water is lost after conveyance to the cropped plot; evaporation takes place from the ground surface or leaves and water may run away without infiltrating. There is, therefore a considerable extent of wastage of water.

As water changes from solid to liquid and to gas throughout the seasonal and hydrological cycle, it is relatively difficult to identify specific units of water. Hence, water presents unique problems in the establishment and enforcement of property rights, which are the essential foundation of any market allocation system (Young, R.A, 1986, P.154). Most users of water consume only a part of it, even within one phase of the hydrological cycle, the remainder being available to subsequent producers or households. Finally, the potential for water quality degradation is another problem difficult to deal within market exchanges of water rights. The economic reasons for the heretofore limited

development of water markets stem from both the varied nature of water use and the relative plentitude of water, i.e., compared to demands. Water consumption is most often thought of in terms of the consumptive and diversionary uses, such as irrigation, and household and industrial uses. Recreational demands for flows, hydro-electric power generation and waste land dilution are also increasingly in demand[6]. A number of these in stream uses represent collective consumption demands, which are partially non-rival in consumption. Such commodities are likely to be under-supplied in a market economy (Randall, 1983, PP.131-148). Most societies have therefore chosen non-market administrative mechanisms for allocation of water.

The second economic reason for the rudimentary development of water markets lies in the apparently paradoxical assertion that water has not been particularly scarce. Even in exceedingly arid climates, additional supplies from mountain run-off or extensive ground water supplies have often been relatively inexpensive. New uses did not strongly conflict with the interests of the established water-consuming groups.

Water is also a bulky commodity, in the sense that the value per unit weight tends to be relatively low. Therefore, costs of transportation and storage tend to be high compared to economic value at the point of use. Hence, only in limited cases it is economical to transport water, and the extensive rail, truck, and pipeline network that the market system has developed to transport high value liquids is absent for water since the market

system seeks profit while developing the related infrastructural activities.

The third major force inhibiting the adoption of market institutions for water allocation can be identified as conflicting social values. The sacredness of water as a symbol of ritual purity, exempts it in some degree from the dirty rationality of the market (Boulding, K.E., 1980; P. 302). Water is so holy and valuable to use as a symbol that it is apt to carry the production and transportation of it far beyond the point of rational economic returns (Boulding, K.E, 1980, P. 309). Some religious teachings may explicitly or implicitly prescribe against market allocations of water[7].

Where markets are absent due to any of the above causes, government regulations may be established to provide for regularity of water use and to protect the given uses against present and future competing demands[8]. This type of protection may preclude economically efficient resource allocation, if demands for alternative uses outweigh the economic value of protected uses.

The Role of Government in Allocation of Water :

The role of government in the development and allocation of different agricultural inputs varies a great deal, from virtually nothing in the case of rural labour to virtually everything in supplying irrigation water from the medium and large-surface

irrigation projects in India. This diversity raises the obvious question as to the need for major government involvement in surface irrigation development in market oriented agricultural systems of the developing countries. So this question lies in the socio-economic, engineering, and institutional aspects of irrigation development (Sampath, R.K, 1992, P.968). The characteristics of surface irrigation water necessitate these aspects since it is being a publicly supplied intermediate input.

For the free market to determine fully the development and allocation of surface irrigation water, there should be a system of pure private property rights. That seldom exists in the real world. The existence of such a system is contingent on certain requirements such as certainty, transferability, externality and competition, being met. The meaning of the terms, is important. **Certainty** refers to the well defined property rights in terms of quantity, quality, location and time of use. **Transferability** refers to easy and low-cost transference of water through purchase and sale. **Externality** assumes that spillover effects on other people's property from water use would be absent or insignificant. And **competition** assumes the existence of competitive focus at both the demand and supply sides of the market respectively (Sampath, R.K, 1992, P.968). In most countries, water rights are based on one of three current systems, riparian rights, public allocation, and prior allocation (Sampath, R.K, 1992, P.968). In the first, riparian rights link ownership of or reasonable use of the water to ownership of the adjacent or overlying land. This system is used primarily in humid areas with

no water shortages. The second is based on priorities of use in which the government allocates water. The third is based on the appropriation doctrine, under which the water right is acquired by actual use over time. None of these systems fulfills all the requirements of pure private property rights. In the riparian rights system, with no allocation priorities, there may be constant court battles over water ownership with the poor losing out to the rich, owing to the high costs of litigation. The conflicts may lead to the need for public or government control or ownership of water, which would enable the government to sell the rights through pricing mechanisms or distribute the rights through administrative rules.

The second reason for the involvement of the government in the development and management of surface irrigation projects is the significant economics of scale which can be gained in the storage, conveyance, and distribution of large quantities of irrigation water. Government management may therefore reduce uncertainty resulting from supply which is highly variable in time, space and quality (young, R.A, 1986, P. 1143-51). These solutions usually involve benefits that are non-rival in consumption and therefore in a sense exhibit the character of public good.

The third reason is the need to effectively deal with externalities, particularly those affecting the environment which arise from the development and management of water resources. For instance, the most promising institutional arrangements are

ones in which those in charge made decisions regarding both environmental services and the resources to be spent on them. At the lowest level, this means letting households choose the services they want and are willing to pay for. At the highest level, it means that the stake holders in a river basin decide what level of environmental quality they want and are willing to pay for (UNO, 1996, P.5). The fourth reason for the involvement of government in the irrigation sector is the attainment of certain social objectives, such as income re-distribution, food self-sufficiency, and sustainable agricultural production. The composition and importance of these objectives could vary a great deal across countries and across projects and regions within a country.

The overall objectives behind government intervention and involvement in the development and management of irrigation in general, and of medium and large-surface irrigation projects in particular, are to achiev economic efficiency in the use of scarce irrigation water resources both at a point of time and over a period of time (Sampath, R.K,1992; P.968). And intervention is necessary to attain the specific equity objectives such as redistribution of income and wealth among individuals, social classes and regions and merit wants such as self-sufficiency in food grains production and sustainability. Economics of irrigation has an important place in the process of planned economic development. Development of irrigation is evaluated according to the efficiency and equity objectives. A comprehensive plan of water development becomes essential in view of the fact that

water resources, available in any economic system, are generally limited and are insufficient in meeting the long-term water requirements of various kinds. In most of the cases, they are unevenly distributed resulting in seasonal abundance or devastating floods in some areas and chronic drought and famine in the other. The competition for the use of water resources is likely to increase in the coming years. It is essential that wastage of water resources are minimized, beneficial uses are assured and the efficiency of utilization of available utilizable water resources is improved. The development of modern irrigation system has become costly. The large irrigation projects transcend river basins and envisages the tapping and harnessing of great rivers for an integrated and optimum exploitation of their irrigation potential. This naturally involves large financial outlays. The feasibility of irrigation projects, therefore, remains conditional to the economic soundness. Hence, the necessity of pricing of irrigation water is considered as financially productive and economically sound. Therefore, the necessity arises for pricing of irrigation water.

Economics of Irrigation Pricing :

The fundamental role of prices is to help distribute the limited goods and services to consumers and to determine the allocation of limited resources among competing uses and users. Pricing of irrigation water influences the efficiency with which the water is supplied and used. It also affects the equity of distribution in terms of income, and cost recovery. A necessary

condition for an irrigation pricing mechanism to improve the efficiency of water use is that there should be some influence on farmers' decisions affecting water use, administrative rationing the irrigation water to the farmer, and to society (Sampth, R.K, 1992, P. 969). Another condition for an irrigation pricing mechanism is to establish systems of revenue generation that are efficient in the sense that the ratio of funds raised to the costs incurred is reasonably high. Efficiency of resource-mobilization is not the only objective, but minimization of administrative and economic distortion should be maintained. Irrigation pricing mechanism raises equity issues that are concerned not only with the magnitude of the distribution of irrigation benefits, but the distribution of income and wealth in general and fairness among individuals.

(a) **Efficiency** :

For practical purposes, one can discuss the efficiency aspect of pricing irrigation water under four situations, the first two pertaining to the short-run, the third pertaining to the medium run and the fourth pertaining to the long run (Small and Carruthers, 1991, pp. 109 - 118). In the first situation, having limited availability of irrigation water, the objective is to maximize the net benefits to society. The social marginal value of irrigation water across different groups of users would be the same. If not, re-allocation of water can increase net social benefits[9].

In the second situation, the problem is to decide whether to increase the supply from the given physical system. The increased variable cost will increase the supply at the margin, but not available for use elsewhere in the economy. This situation is justified in increasing the supply if the additional social benefits exceed additional social costs[10]. In fact, it will be appropriate to increase the supply up to the point at which marginal social benefit equals marginal social cost.

In the third situation pertaining to the medium term, it is the question of expanding the supply system by allocating capital resources to bring in new irrigation projects. Such additional investments are warranted if the social returns exceed the social costs of those investments at the margin to expand the given resources for further development.

In the fourth situation pertaining to the long-run, it is the problem of deciding the optimum level of investments in the irrigation sector vis-a-vis investments complementary to or substitutes for the use of water such as water conservation projects. When water is very scarce, or if marginal cost is very high, water losses are reduced by carefully preparing the land and maintaining the field channels[11].

In all the above situations, water pricing can play a critical role in determining the levels of demand and supply and the amount of resources invested. Market systems clearly show that if perfectly competitive conditions are satisfied and externali-

ties are absent, the market prices will reflect social values. And if the long-run marginal cost pricing is followed in the pricing of irrigation water, then the corresponding levels of investment in irrigation projects and the resulting social benefits will all be optimal. Marginal cost pricing would not be optimal if there are externalities or increasing returns to scale in the irrigation sector, or there is monopoly in a sector with which irrigation is closely linked, or other imperfections and distortions are present in the market. The pricing structure that can be adopted depends on the nature of the delivery system since the method by which water is delivered will affect the certainty, adequacy, timeliness and quality of water, and consequently the feasibility of different pricing systems. The four common methods of delivery are continuous flow, rotation, demand and closed pipe systems. Volumetric pricing is feasible under the demand and closed pipe systems. These methods are applied in Indonesia, Japan, Malasia, Nepal, Korea, Sri Lanka and Singapore. It is extremely difficult under a rotation system and almost impossible under the continuous flow system. In general, demand and closed-pipe sprinkler systems are more than expensive and their usefulness in irrigating paddy crops is yet not fully utilized, due to this reason, the rotation and flow systems are maintained efficiently to some extent through command area development mechanisms especially in India, Bangladesh, Pakistan and China.

Although efficiency is an useful concept, its focus is on producing a package of goods in an optimal fashion, ignoring the

question of how the goods or the income associated with their production are distributed. This brings us to the second broad criterion of economics of equity.

(b) **Equity :**

It is worth noting here that there are different concepts of equity used in the literature. First there is the equity in income distribution in terms of inter regional, inter-personal and inter-class categories, and then equity in the sense of equitable system of charges with regard to the services received and costs imposed on consumers and producers (Small **et.al.,** 1990, pp.119-134). There are issues relating to using different criteria such as the ability to pay principle in terms of wealth or income basis, the benefit principle in terms of the value of water to the consumer, the supply cost principle in terms of the economic costs that their demands impose on the system and thus on the society. And finally, the historic cost principle based on cost as they were incurred rather than as they are incurring (Sampath, R.K. 1992, P. 970). Which of these concepts is used in any particular context will have implications for efficiency in the use of irrigation water at a point in time as well as over a period of time. In addition, there is no unique way of choosing among these concepts since objectives vary across regions, crops and users and over time. So in any country, more than one concept may be used simultaneously in different projects and regions for valid reasons. The conventional notion is that the equity objective always conflicts with the efficiency objective owing to

political power of various interests. But there are conditions under which promotion of efficiency will in fact improve equity. Some times policies introduced to promote equity resulted in not only decreased efficiency but also, worsening of the degree of equity (Sampath, R.K., 1992, P.970). The situation where it has found the overall per hectare productivity of land is inversely related to the size of operational holdings because of the more intensive of land, labour and other inputs per unit of land by small holders.

The empirical information shows that irrigation development and distribution based on the proportional equality principle not only decreased efficiency but also resulted in worsening the inequity problem. In situations where small-holders do have higher productivity per unit of land, allocation of water based on efficiency criteria would help small forms to gain a greater share of water than allocation based on the proportional equity principle through water user associations, for example, several parts of India. Thus, under certain conditions, there may not be any conflict between efficiency and certain kind of equity objectives. Under these conditions, setting price levels may play a key role to achieve these objectives. Water pricing methods vary considerably across developing countries and within a country they vary from one project to another and from one region to another[12]. Mostly, these pricing methods are based on financial rather than economic considerations. This leads to the setting of price levels that will accomplish the most efficient use of scarce irrigation water.

The Level of Irrigation charges :

Prices are charged for two reasons. One is financial. Enough money must be raised to pay the cost incurred in providing a good or services. The other is economic. The quantity of goods people buy depends on the price. If the price exceeds the marginal cost, full economic utilisation will be prevented. If the price is less than the marginal cost, an apparent demand will suggest an expansion which can not be justified on economic ground. Only if price equals marginal cost will market forces encourage the economic level of production.

In a broader sense,pricing also has a social function related to the multidimensional nature of social welfare (Marglin S.A., 1966, pp.88-92). In addition to affecting economic efficiency, price levels influence income distribution, economic stability, the foreign trade balance, and other social goals. Prices can be reduced to effect income redistribution, encourage more rapid utilization of project output during the buildup period, encourage substitution of project output for imports to improve the trade balance, and encourage reinvestment by project beneficiaries.

The financial and economic functions of charges are satisfied simultaneously under pure competition.[13] The market reaches an equilibrium point where the long-rum marginal cost equals the marginal benefit (see figure 2.1) to fix the price P and the output Q. Because of this intersection marginal cost equals

average cost, the product of P and Q equals the total cost and the financial requirement is satisfied. Because the marginal cost equals the price, the economic requirement is also satisfied.

Where the economies of large-scale production are large or total demand is small, the optimum scale[14] of plant may be almost as large as total market demand (see figure 2.2). The optimum Q is still determined by the point where marginal costs equal marginal benefits. The price satisfying the economic requirement is P_1. However, only the average cost P_2 of producing Q need be charged to satisfy the financial requirement. Marginal cost pricing will produce a profit equal to $(P_1 - P_2)$ Q, which if large enough, may justify an additional production unit. If demand is smaller than the optimum production - unit size, the marginal-cost curve exceeds marginal cost (see figure 2.3). The price P_1 will satisfy the economic requirement. However, the price would have to be P_2, or the average cost, for the financial requirement to be satisfied.

Under conditions of increasing average cost (at the market - determined level of production), a charge fixed by the economic requirement more than satisfies the financial requirement. Under conditions of decreasing average cost, there is a dilemma (see Jack Hirshleifer, **et.al.**, 1960, pp.88-93). Marginal cost pricing P_1 does not raise enough revenue and average - cost pricing P_2 restricts economic use. Some compromise between the conflicting requirement is required.

Reconciling Economic and Financial Requirements:

Three alternative approaches are available for reconciling economic and financial requirements. One possibility is to employ price discrimination to capture some of the consumer's cost, the total benefit may exceed the total cost P_2Q eventhough only P_1Q can be recovered by marginal cost pricing. The goal in price discrimination is that those benefiting by an amount exceeding P_1 be charged an extra fee in order to satisfy the revenue requirement. The result is a marginal cost fee plus a surplus fee which varies with the value the consumer derives from use of the output. In practice, it is difficult to discriminate among individual users, and the result is price discrimination by user group. A typical price discrimination is to charge industrial users more for water than agricultural users. Although such price discrimination produces economic inefficiency by restricting economic marginal industrial development while permitting full economic agricultural development, it is a reasonable compromise between the economic and the financial requirements.

The second approach is to find an outside benefactor willing to subsidise the project by the amount (P_1-P_2) Q. In water resources planning, the benfactor is usually the government. While this approach satisfies the revenue requirement, it distort economic resource allocation by diverting, to the project, tax funds which have greater value in other uses. It redistributes

income from those paying the taxes to those receiving the subsidy.

The third approach used to raise the revenue (P_1-P_2) Q while maintaining marginal cost pricing is to levy a non-marginal charge or tax on those using the output. Each user would pay a flat fee independent of the quantity used plus a charge per unit of use. The unit charge would equal the marginal cost, while the flat fee would be set to raise the balance of the required revenue. The non-marginal levy may be assessed in various ways. For the example of irrigation water, an equal sum could be charged to each user, a charge could be made proportional to farm size, or a charge could be made proportional to farm value.

Setting of water charges :

Pricing policies are generally motivated by national objectives of achieving economic efficiency and income distribution. If the goal of a pricing policy is economic efficiency, then economic principles must apply (UNO, 1996, P.5). In a strictly economic sense, a water user can afford an irrigation fee as long as that fee is smaller than his or her additional net income (prior to paying the fee) that is attributable to irrigation (Small and Carruthers, 1991, P.160). If the goal is to redistribute income to particular groups, then the principle of subsidised (socio-political) pricing is used. The economic efficiency goal is generally pursued in countries which subscribe to the policy that water should be treated as an economic good. These countries include, Indonesia, Japan, Malaysia, Nepal, Papua New

Guinea, the Republic of Korea, Sri Lanka and Singapore. Income distribution remains an important goal in countries where water is defined as public property; such as Bangladesh, China, India, Myanmar, Pakistan, Philippines and Thailand (UNO, 1996, P.5).

Most legal systems set in greater or less detail the basis for payment for water. Usually only the general principles are given in the statues and the details are left to regulations or by-laws of the organisation supplying water. Several principles of setting of water charges[15] are outlined below.

Cost of service:

Cost of service is the traditional method of pricing of utilities, including water utilities. In each system, price is related to the cost of providing the specific service is the cost of capital, administration and operation and maintenance, costs properly charged to water production. Where as investor-owned utility is the supplier, a return on investment is also included in the price structure. Cost recovery is usually through water tariffs and taxes. Where public agencies raise capital for construction through issuance of bonds, the security, and even the source of bond repayment, is likely to be the property tax base of the issuing authority (UNO, 1996, P.8). In such cases, the price of water paid as a tariff by the user may cover only the operation and administration costs. Where large capital investment are required and a long build-up period for water use occurs, the combination of taxes and tariffs tends to equalise the annual unit water charges.

Ability to pay:

Pricing water on the basis of ability to pay is a method for society to redistribute income. Prices are set at less than the cost of supply for a class of user or a purpose of use. Revenue shortfall in such situations may be subsidised or provided from other classes of users. This method of pricing water is applied only to users who can not meet the full cost of service (Small and Carruthers, 1991, P.162). For many public irrigation pro-jects, an investment is made only after analysis has shown that a proposed project can be expected to provide a satisfactory economic return. For goods or services where market prices do not reflect social opportunity costs, shadow prices (estimates of their opportunity costs to society) are used in the calculation of the economic return. Where these shadow prices differ sharply from market prices, it is possible that the water users could not afford to pay for the total cost of irrigation even though investment shows a favourable economic return to the irrigation. And one more significant administrative complication that may make it difficult for a public agency to collect the cost of irrigation services from the water users, even if they can afford to pay for it. Typically, the per hectare irrigation benefits received by individual farmers within a single irrigation project will vary considerably both from year to year and for any given year, from place to place within the project. It is generally not practical for a public agency to determine what benefits each individual farmer receives, and to adjust the irrigation charges accordingly. Rather, some general fee structure must be estab-

lished and applied to all the water users. For these two reasons, the ability to pay principle is a method for society stressing need to redistribute income.

Opportunity cost:

Opportunity cost is a method of pricing sometimes proposed when public investments are made for water development projects. Under this concept the charges for water are set to recover the "true" cost of the investment, which is the value to society that could be achieved if the same investment were made else where or benefits realised from alternative opportunities that must be foregone. This assumes that the benefits can be quantified. By pricing water at rates to recover the opportunity costs, the real value to the consumer is tested in his willingness to pay and the quantity consumed (UNO, 1996, P.8). Although the pricing of private goods may be driven by opportunity costs, this mechanism has not been used for public water development projects. An exception might be where an investor - owned utility is a water supplier and the return on investment in water supply facilities is sufficient to preclude alternative investment. Rates charged by the investor-owned utility are usually regulated by the government, which generally allows for a fair rate of return by the utility on its capital investment.

Incremental or marginal cost:

Incremental (or marginal) pricing sets the rates equal to the cost of producing the last unit of water supply. The lowest

cost for a supplier is usually developed with increasing costs for additional developments (Small and Carruthers, 1991, P.90). This method places the burden increased demand on those that cause the increase. However, this mechanism is usually not practical as such consumers are not separately identifiable. In practice the supplier molds the costs of water from sources into a uniform rate. Exceptions might occur where facility extension is involved to meet the needs of a particular user. The general use of marginal cost pricing throughout the economy would require large government subsidies in many sectors. This is because marginal costs often below average costs - a situation that occurs when the average costs of a firm (or of an irrigation agency) decline as the size of the firm increases. This would probably be the case in much of the distributive sector of the economy. Full adherence to marginal cost pricing would thus require a considerable expansion in the scope of activity of the government.

Market-driven pricing:

Market-driven water pricing is based on the argument that a decentralized market system allows actual users to balance the value of their use against the value of potential uses by others. Prices are allowed to fluctuate, reflecting supply and demand. A full market pricing system requires that water rights laws be restricted such that the right to use the water may be sold or transferred to others at an amount sufficient to provide an incentive to forego their current use.

The Net-Benefit principle:

Sometimes turned the rent principle, the Net-Benefit principle seeks to employ charges to capture part or all of the economic surplus accruing to the user. It is consistent with the view that water and its fruits are the property of the state. According to this principle, the rate should form some fixed portion of the difference between the additional yield resulting from the irrigation and the additional expenditure (other than irrigation charges) incurred in the process (National Council for Applied Economic Research, 1959, pp.71-2). In other words, irrigation rates should be based on the additional net benefit available to the cultivators from the use of the water supplied. The logic behind this criterion is that since the demand for water depends on the willingness of the cultivators to make use of it, amount of net profits of the newly added farm products available to the cultivator can only be charged in the form of water rates.

Policy of free of services by the Government:

Provision of Government services free of any charge can be justified in case of basic and essential services. However, education, severage and garbage disposal etc., come under this category. But services like irrigation, if water is supplied free of cost, there is every chance of mis-utilisation by the cultivators. Therefore, the advocates of this principle call it "promotional policy" and they recommended a concessional water to promote agriculture through irrigation. The arguments run as follows : firstly, the direct beneficiaries of irrigation over

the poverty stricken terming millions of peasants with legendary low capacity to pay taxes and as such, they should be made to pay at lower rate. Secondly, irrigation creates externalities in the economy besides benefiting the irrigators directly. It is no gain saying that irrigation by facilitating the adoption of both intensive cultivation and improved agricultural technology has helped agricultural productivity to increase (Ansari, N. 1986, pp.40 to 73). Therefore, this principle contend that the entire economy should make some contribution towards the cost of irrigation by subsiding it from general revenue and as such, irrigators should be charged only concessional water rates. Under this approach, however, there is no specific basis for the fixation of water rates, such as, the cost of supplying the water or the quantity of water supplied. This system enables the irrigation to take as much water as the lives. The result is over irrigation and misuse of water.

Economists normally address the question of right price for water mainly from the efficiency point of view and conclude that as long as excess capacity exists, the price of irrigation water should equal the marginal cost of providing it but whenever a capacity constraint exists the price should be allowed to rise above marginal cost to the point where quantity demanded just equals available supply (Small and Carruthers, 1991, pp.90-95). This is nothing but marginal cost pricing, i.e., setting the price of a product equal to incremental cost associated with incremental production. Economic theory clearly states that in a situation (irrigation project) where marginal cost is continuous-

ly falling with the size of the unit it will remain below the average cost throughout and any price fixed on the basis of marginal cost under such condition will not cover the full average cost and will thus necessitate subsidisation.

Financing these subsidies by the state will bring about inefficiency in the economy which it is argued, may not be over come by meeting the subsidies through income tax owing to likely distortion in allocation of time by the tax payers. Under the circumstances, average cost pricing with no subsidy appear to better alternative to marginal cost pricing. It is however, argued that a marginal cost pricing incorporating two part tariff, one based on marginal cost and the other a lump sum charge levied would also eliminate the need for subsidy. In any case, marginal cost pricing may not increase the economic efficiency of allocation of irrigation water if other prices in the public/ private sector of the economy are not set at the marginal cost of production. Because there are indirect beneficiaries such as the consumers who benefit as much or even more than the direct beneficiaries of irrigation. Marginal cost pricing has other practical problem too, apart from the theoretical considerations. Firstly, it will change with the nature of irrigations decision with which the irrigation agencies are concerned. Secondly, marginal cost of irrigation generally varies over both space and time which will result into different prices being charged at different area and at different times. For instance, seasonal differences in the availability of water may create differences in marginal costs, the marginal cost to society to delivering one

unit of water to the farmers at the tail end may be higher than the same to the farmer nearer the source of water supply. Price based on marginal cost, under these circumstances, would necessitate charging varying prices within a single irrigation system and also over time. This would violate the requirement of equating marginal benefits to all users, and since other things are not equal such spatial and temporal price differentials would lead to economic inefficiency (Small and Carruthers, 1991, pp.39-56). Thirdly, marginal cost pricing will require volumetric measure of water delivered to the farmers. This practice is no where in the country due to extra cost escalation problem may arise. Notwithstanding the arguments against functional difficulties of marginal cost pricing the fact remains that the existing water rates are abysmally low need to be enhanced with immediate effect so as to improve financial health of the state irrigation departments, and also to reduce and eliminate substantially the burden of irrigation subsidies on the government.

Conclusion:

Considering the above principles to water rate fixation, the promotional policy was appropriate when food production was lagging for behind its consumption in India during the initial years of planning. But there has been commendable achievement in our agricultural production in the recent past. It is a well-known fact that agricultural sector is under-taxed and a such, most part of the benefits from larger agricultural production remains with the farmers. Therefore, there is no justification for charging a nominal promotional rate for irrigation water.

Further, with promotional water rates, it becomes an 'imperative necessity for irrigation projects to incur deficits. The states have been investing heavily in irrigation during the planning periods, as a result of which, their losses been unmanageably large. Not only the states are discouraged to make further investments in irrigation, but also maintenance and repair of the existing projects have become a problem. Since the benefits of irrigation, such as higher crop yield and larger net farm income are both quantifiable and substantial, it is reasonable and fair that irrigation water be sold not at nominal rates.

The foregoing analysis discussed about the determinants and fixation of water rates. There are contrary pulls developed in regard to rate fixation; one emphasised the need to raise rates to recoup all the costs and the other pleaded for keeping down the level of rates to facilitate full utilisation of newly created capacity. As Ansari stated, there is need from the long term point of view to cover the costs and is not subsiding irrigation by the state. The marginal cost pricing, the average cost pricing and the net benefit principles are not suitable due to unutilizable capacity of irrigation exists. Considering the above, the most rational water rate policy appears to be the one under which the water rates are fixed at a level such that the irrigation schemes do not impose a burden on the state exchequer.

In other words, the financial returns should not only cover working expenses but also a specified percentage of interest on

the capital investment. The Eighth Five Year Plan document and Vaidhyanathan Committee report were also stated, that reintroduction of "financial return criterion for projects", starting with recovery of operation and maintenance costs plus 1% on capital outlay be-reintroduced.

To conclude that water rates on the basis of gross income of the farmers from irrigated crop as a suitable basis of irrigation rates in Andhra Pradesh. This variable is easily quantifiable in the regions and also suitable for where unutilisable capacity of irrigation exists. The projects where ancillary facilities are lacking, the farmers are not free to raise the desired crops due to insufficient supply of water, and hence they obtain lower incomes compared to their counterparts in the **ayacut** where such facilities are available.

NOTES:

1. The most visible aspects are the policies of government which set for the bureaucracy the objectives of irrigation management. For example, how much effort should system managers devote to regulating water use in head-end areas in order to have more water to give to downstream areas? Assessments will be affected, for example, by whether government leaders are (a) stressing food self-sufficiency as a production goal, (b) minimising expenditures to reduce a budget deficit, or (c) enhancing opportunities for the disadvantaged to create a more equitable society. The implementation of cost-recovery program would be quite different under each of these three policy conditions (Uphoff.N, **et al**, 1991 pp.98-99).

2. In developing countries, more and more people are focusing their recreational activities around lakes, rivers and seas. In India, as incomes and leisure time grow, water-based recreation is becoming increasingly popular and an adequate supply of good-quality water helps provide a basis for attracting tourist trade (F.A.O., 1995,pp.247-255).

3. For example, the enjoyment of an attractive water body does not deny similar enjoyment of resources to exclude unentitled consumers from using the good. Exclusion costs are frequently very high for water services such as flood control projects and navigation systems. Goods and services that are non-rivals in consumption are normally better suited to public sector interven-

tions, including ownership, provision and regulation (Food and Agricultural Organisation, 1995, p.259).

4. Total public expenditures for irrigation for many countries in Asia declined significantly during the 1980s. Annual expenditures in China and Sri Lanka were cut nearly in half between the late 1970s and the late 1980s. In Philippines annual expenditures on irrigation in the late 1980s were only one-third the level of the early 1980s. Declines in the late 1980s from peak expenditure levels in Bangladesh, India, Indonesia and Thailand range from 15% to 40%. What has caused this decline in the rate of irrigation investment, contributing factors include the large public and foreign debt loads carried by most of the agriculturally based economies in the region, the declining share of unexploited irrigation development potential in many countries in the region, and political resistances from environmental interests and those displaced or otherwise negatively affected by irrigation development. However, the main reasons for declining investment are the decline in world prices and the increasing real costs per hectare of new irrigation development (Mark W. rosegrant and Mark. Swendsen, 1993, pp.20-21).

5. Farmers are generally aware of the benefits of collective goods and services. They would vote for politicians who promise to provide them. But in some situations, the public may be unaware of the real benefits of an investment. In this case, a wise government may choose to promote the production of some goods above the level the market would dictate. Such goods are

said to be merit goods, and to reflect merit wants. Merit goods are usually reserved for items such as health care of education services where consumers may not fully appreciate the potential benefits. In the irrigation field drainage is an area that might deserve merit good status. Farmers may not fully understand that the short or long-term yield is depressed by the impact of waterlogging and salinity in the absence of costly drainage facilities. Another example arises in the provision of public health protection on irrigation schemes, where the risks of water-related diseases such as schistosomiasis and malaria are not fully understood by beneficiaries. For this reason government may be satisfied in providing a level of medical protection above that which farmers would "purchase" for themselves (Small and Carruthers, 1991, P.28).

6. The general paucity quality coal and mineral oil in India is somewhat compensated for by the vast hydel-power resources. In potential water-power, India comes after the Republic of Zaire, the Russia, Canada and the United States. Based on the normal flow of water, India's water-power potential has been estimated at over 40 million kilowatts. Nearly 60% of India's potential water power resources lie in the Himalayas. A little over half of these resources fall within the basins of the Brahmaputra, Manipur and Tayo in the north-eastern part of the country. Over a quarter of the potential water-power resources of the Himalayan region belong to the Indus and its tributaries within the Indian Union, the rest being within the Ganga-Brahmaputra Basin. About 20% of the potential water power resources of India lie within

the basins of the east-flowing rivers of South India. The remaining 20% are equally shared by the west flowing rivers in the western Ghats and by those of Central India. Although there are several sources from which power is generated, hydroelectricity is by far the most significant. Unlike coal, mineral oil, natural gas and atomic minerals, running water is the only major source of energy at present which is replenishable (Prakash, B.S., 1988, pp.60-62).

7. In India, the Hindus treat water as a holy one and take holy baths during **pushkaras** of the twelve respective holy rivers with the belief to attain **moksha** by doing so.

8. Individual irrigation farmers generally recognise that the collective interest is served by strong management that enforces rules. Furthermore, they understand that if all follow these rules their aggregate individual benefits are maximised. (Leslie E. Small and Ian Carruthers, 1991, p.205.)

9. Social benefit means the sum of the gains or benefits deriving from an activity or project to whomsoever they accrue. These are the relevant benefits for inclusion in cost-benefit analysis but should not include transfer payment (Pearce W.David, (ed.,) 1986, p.391).

10. The social cost of a given output is the sum of money which is just adequate when paid as compensation to restore to their

original utility levels all who lose as a result of the production of the output. The social cost is the opportunity cost to society rather than just to one firm or individual (Pearce, W.David, (ed.,) 1986, op.cit, P.391).

11. For example, irrigation projects in parts of India and Pakistan operating under the **Warabandi** system of water distribution were designed to spread a limited supply of water which is meant for water losses are reduced (Small and Carruthers, 1991, op.cit., P.81).

12. For example in India, the system of irrigation water rates in various states of the country is as diverse as the culture and the people. Rates have been fixed considering a number of factors, sometimes without any rational and objective consideration, and are seldom revised. This has led to considerable divergence, inter-state and even intra-state. Major factors leading to variation of water rates are geographical unit, system of irrigation and crop and season (Zafarul Hasan, 1996, p.49).

13. A Market structure is perfectly competitive if the following conditions hold ; there is a large number of firms each with an insubstantial share of the market. These firms produce a Homogeneous product using "identical share of the market. These firms produce a Homogeneous product using "identical production processes and posses perfect information. It is also the case that there is Free Entry to the industry, that is, new firms can and will enter the industry if they observe that greater than Normal profits are being earned. The effect of this free entry is to

push the Demand curve facing each firm downwards until each firm earns only normal profits, at which point there is no further incentive for new entrants to come into the industry (Pearce, W.David, (ed.,), 1986, p.323).

14. The "best" situation or state of affairs. for example, the choices made by consumers are analysed in terms of attempts to obtain the optimal pattern of consumption (Pearce, W.David, (ed.,) 1986, p.311).

15. The rates or prices set have both resource allocation efficiency and equity impacts and influence the level of agency revenues. For a better appreciation of the problems involved in the fixation of water rates, a discussion of the pricing policies of public enterprises is imperative (see figure 2.4) :

The curve MB represents marginal benefits or demand for water reflecting marginal willingness to pay. Marginal cost (MC) represents the incremental cost of supply. The Pareto optimal pricing policy, as is known, would use MC as the price schedule.

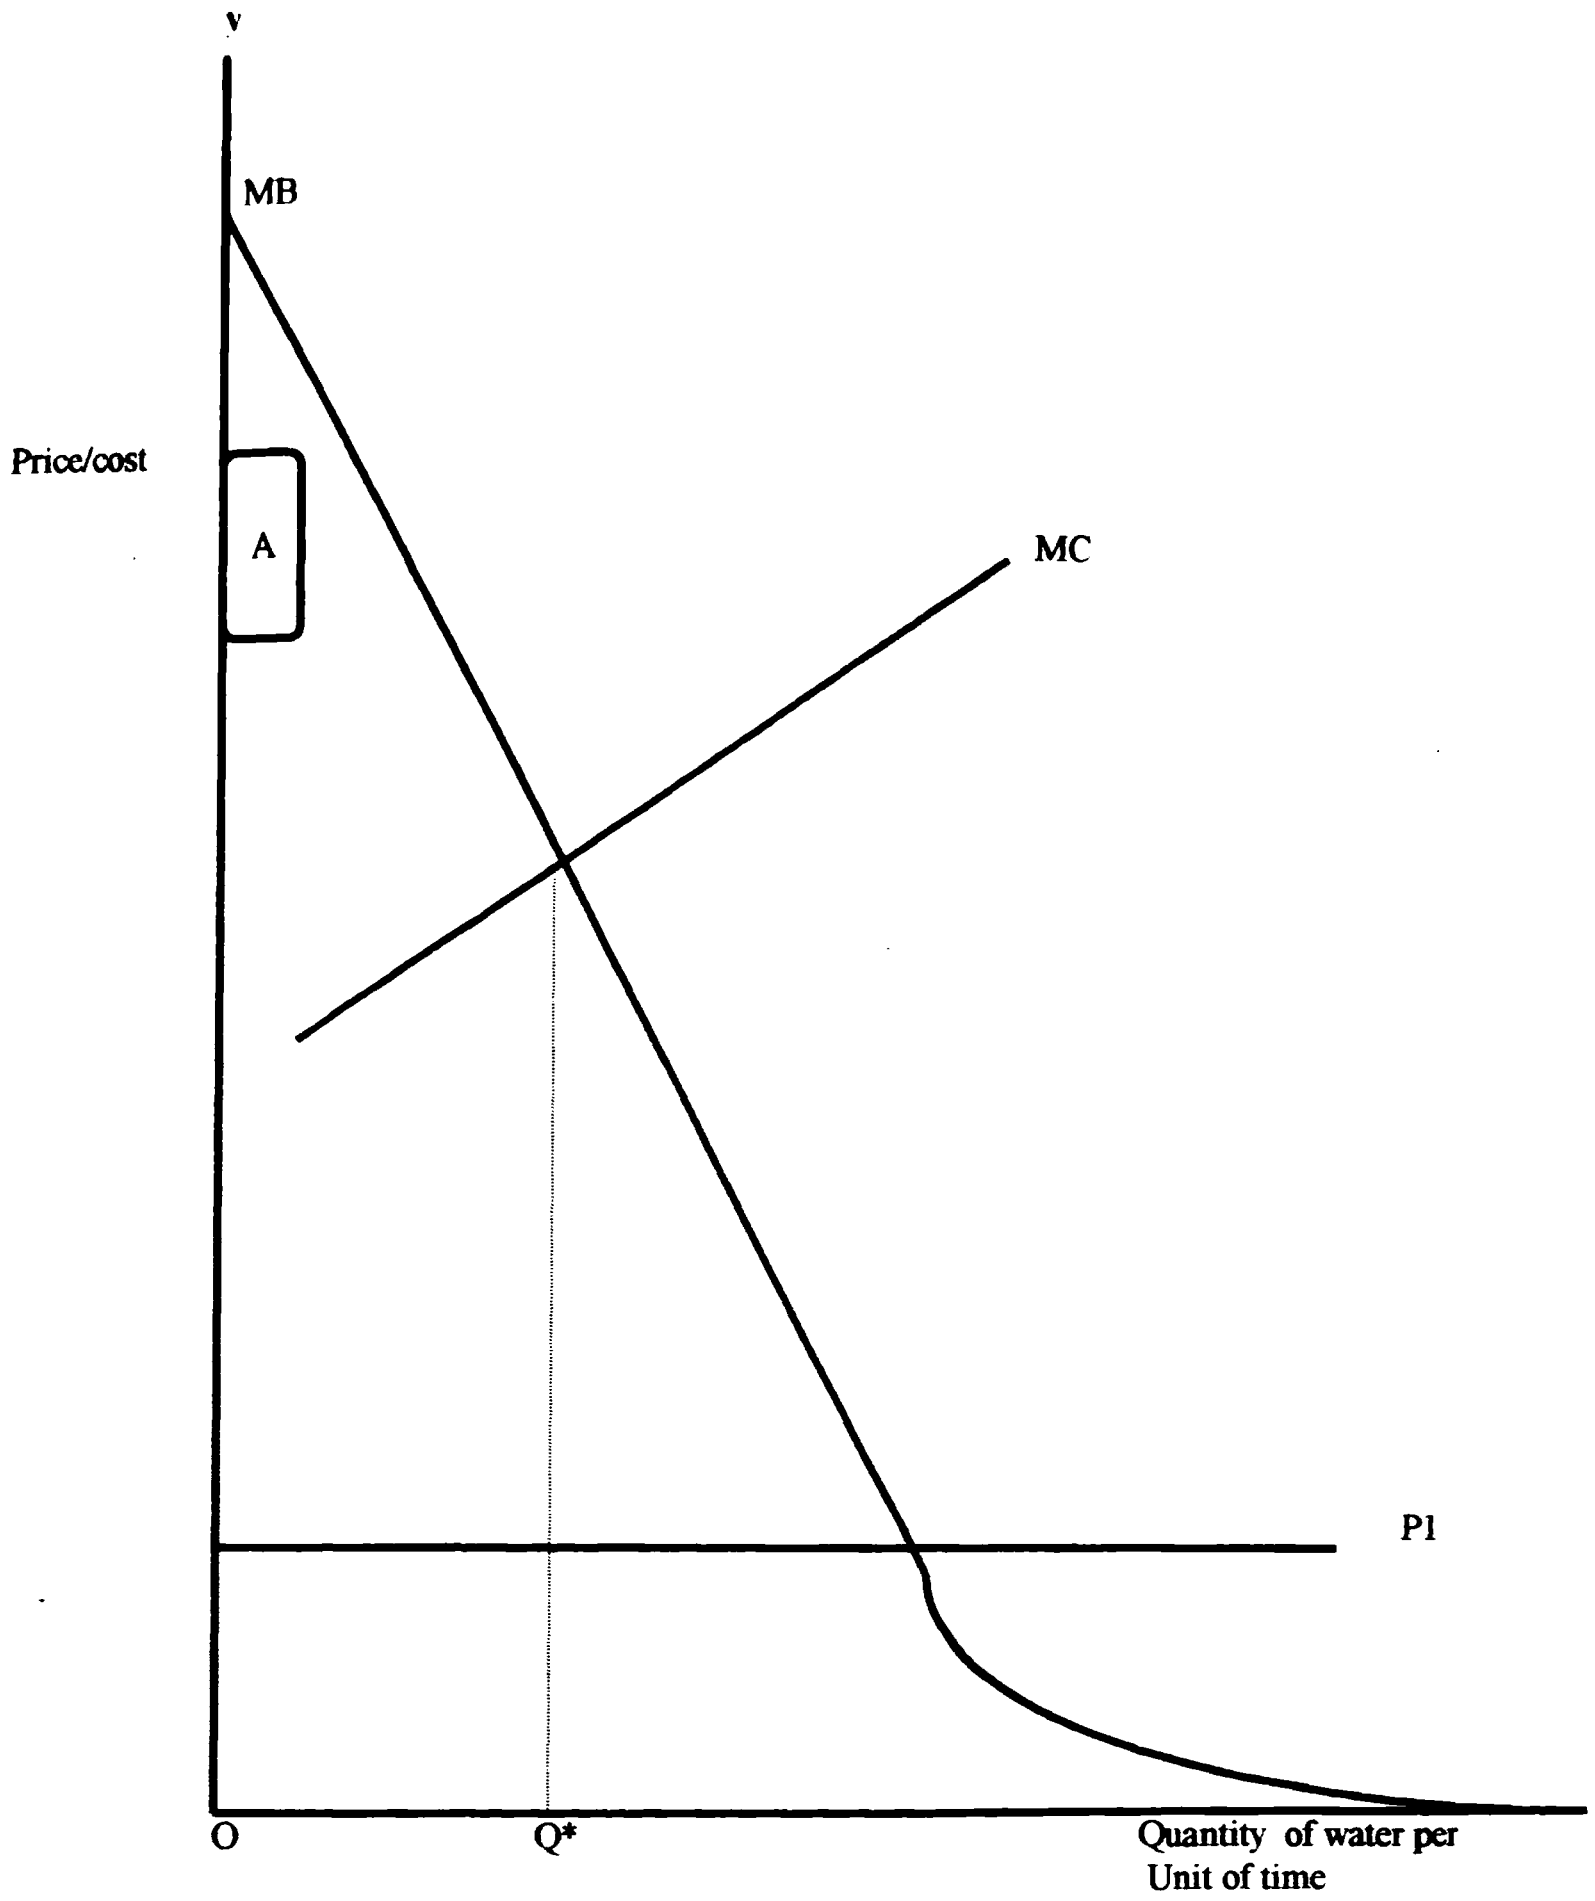
P = Mc

The optimal quantity to supply and consume is found by equating marginal cost with marginal benefit (or) marginal value.

MC = MB

At the point, labeled Q* in above figure, the willingness to

FIGURE - 2.4



Source: Yourng. R.A., 1986, p. 157.

pay for the marginal unit exactly equals the opportunity cost (willingness to pay for foregone opportunities). Any consumption greater than the optimal level will involve marginal units whose worth to the user is less than the incremental cost of supply. Conversely, price policies which constrain use below Q* will create a situation in which the value of additional units exceeds the cost of supplying them. A principal theorem of micro economics shows that, in a properly functioning competitive market, price will equal marginal cost.

Following a marginal cost pricing policy from an economic efficiency point of view, conflicting revenue and income redistribution objectives often dictate alternative solutions (In perfect competition alternative solution is profit maximization, and in imperfect competition it is taxation or regulation). The allocative impacts of two broad alternative classes of rate-setting rules can be analyzed. Consider the line P1, which represents a volumetric price set below marginal cost line P1 can be set at any level, the only constraint being that it can not exceed the maximum willingness to pay, represented by the vertical intercept of MB. Allocative efficiency losses are incurred to the degree that P1 differs from MC. The box labeled `A' in above figure, represents a non volumetric rate system which is the most commonly observed method of charging beneficiaries. This approach charges for access to water supply but does not measure or collect for incremental consumption units. Consumption of water by their own intention, fully informed water users under such a system would be predicted to occur at the horizontal demand

intercept. Water use would be rationed only if the charges exceeded total willingness to pay, measured as the area under MB. (Young, R.A. 1986, p.157).

CHAPTER - III

INDIA'S WATER RESOURCES

Introduction:

Economic development of each region within a country is essential to the maintenance of national unity and achievement of satisfactory levels of living. Development and management of water and the related land resources on a satisfactory level are essential for the achievement of the required rate of economic development. Owing to the growth of population and economic activity, the demand for water has increased while the quality of water has often deteriorated. Good quality water has become a scarce resource in most countries.

World Water Resources :

The world consists of one-third land and two-thirds water[2]. The rich potential of the world which lies in water, (i.e., two-thirds) is not exploited at all, though stray attempts are being made by technologically and economically developed countries for increased agricultural production (Shiklomanov, I.A.1993, P.13). As such, land to be cultivated and irrigated remains only within the one-third area of the globe. The water resources in this one-third land area consists of surface and ground water. Nine-ty-seven percent of the world's water is contained in the saline

oceans; of the remaining 3%, about 69% is in the form of snow and ice. Fresh water for human use, found in lakes, swamps, and rivers, makes up only 0.008% of the Earth's water (Shiklomanov, I.A. 1993, P.13). The water cycle renews the flow of rivers, ground-water, and glaciers and the actual run-off from these sources might exceed 47,000 cubic kilometers per year. This shows the scarcity of the usable fresh water on earth.

While the oceans of the world contain a seemingly unlimited supply of water,fresh water for human use is a finite, and fragile, resource. The demand for fresh water continues to grow with the human population. The diversion of fresh water to supply agricultural,industrial,domestic and municipal needs stretches the hydrological systems,both natural and man-made to the limit[3]. Within a nation,these needs compete for a supply of fresh-water that may already be scarce and may vary drastically both seasonally and geographically (Shiklomanov, 1993; P.13). To modify such seasonal and geographical variations, humans have built thousands of large dams (36,000 or more over 15 meters in height) by the 20th century. They impounded more than 5,000 cubic kilometers or about 11% of fresh water, and the total is expected to rise to as much as 7,500 cubic kilometers by the year 2000 if current plans for dam building are carried out.

Fresh water is unequally distributed among the countries and people of the world. Although global renewable water resources average to about 7,420 cubic meters per capita per year, many contries have far more limited resources (see Table 3.1). Asia

accounts for over large amount of renewable water resources followed by South America and North and Central America. Asia accounts for over one-half of the world's annual water withdrawals. Globally, most water is used for agriculture about (69%). This reveals the importance of irrigation which consumes large amount of fresh water. India's position in Asia presents a grave concern in view of the rising levels of pollution and increasing population.

TABEL - 3.1 FRESH WATER RESOURCES AND WITHDRAWALS - 1992

CONTINENT	ANNUAL INTERNAL RENEWABLE WATER RESOURCES		ANNUAL WITHDRAWALS			SECTORAL WITH DRAWALS (%)

Water Scarcity :

Most countries facing chronic water scarcity problems are in North Africa, the near East and sub-Sahara Africa. Countries with less than 2000m^3 per-capita face a serious water scarcity situation, with major problems occurring in the drought years. In many countries, where scarcity is not a problem at the national level, serious water shortages are causing difficulties in specific regions and water-sheds. These countries include, northern China, western and southern India and parts of Mexico. Under-utilisation of irrigation potential leads to unequal distribution of water across canal commands. With plenty of water resources available, at national and regional level in a particular country, inter-state disputes of water arise for untapped potential utilisation of irrigation water.

Human actions may bring about water scarcity in three ways (i) through population growth, (ii) misuse, and (iii) inequitable access (F.A.O., 1995, P.236). Population growth contributes to scarcity simply because the available water supply must be divided among ever increasing number of people. Every country has a more or less fixed amount of internal water resources, defined as the average annual flow of rivers and aquifers generated from precipitation. Over time, this fixed internal renewable supply has to be divided among more and more people, eventually resulting in water scarcity. Thus, the increasing population may induce undue demand on water sources in most of the Asian countries.

World water use :

The early civilizations of Asia,Africa and Latin America organized co-operative efforts to develop river valleys for irrigated agriculture. Through irrigated technology,societies controlled and manipulated the natural water supplies to improve crop production. The result was often reliable and ample food supplies which led to the creation of stable agricultural villages,the division of labour and economic surpluses(Shiklomanov, I.A., 1990, pp.41-43). In today's world,agriculture still accounts for the majority of water use. Globally, around 69% of water withdrawals are for agriculture (see table 3.2). Domestic and industrial uses consume the remaining 31% water uses differ greatly depending on its access,quantity, quality and socio-economic conditions.

Table 3.2 Sectoral water withdrawals, by Income group

Country Income group	Annual withdrawals per capita (m3)	withdrawals by sector (percentage)		
		Agriculture	Industry	Domestic
Low-income	386	91	5	4
Middle-income	453	69	18	13
High-income	1167	39	47	14

Source : World Bank, 1992. P.83.

Agricultural water use is higher as a proportion of total water use in the low-income countries (91%) than in the high income (39%) (see Table 3.4). Nevertheless, on a per-capita basis,the

high income countries use more water for agricultural purposes than the low-income countries.

Global water consumption has increased almost tenfold between 1950-1980 (see table 3.3). Agriculture's share, which was 90% in 1900, is likely to be dropped to an estimated 62% by 2000. During this period, industrial consumption may grow from 6% to 25% While consumption by cities may be increased from 2% to nearly 9% by 2000 A.D, around 35% of the available water supplies will be in use compared to less than 5% at the beginning of the century (Shiklomanov, I.A, 1990, p.20). Quantity and quality of water requirements also differ widely depending on the type of use. Therefore, neet agricultural requirements are especially large in relation to other uses.[4]

Table 3.3 : GLOBAL WATER CONSUMPTION BY 1900 TO 2000 (CUBIC KELOMETERS)

YEAR	AGRICULTURE	INDUSTRY	DOMESTIC / MUNICIPAL
1900	500	40	60
1950	1200	200	75
19080	2250	700	200
2000	3400	1300	400

Status of Irrigation :

The continent-wise status of irrigation shows wide ranging fluctuations in the % of arable land available and the % of irrigated area to the total geographical area (F.A.O, 1990, P.31). The data relating to a country's geographical area, arable land and irrigated area in the world in 1989, total geographical area, the arable land and the irrigated area form 10.25 and 1.73% respectively (see Table 3.4). Of the arable land in the world, the area covered under irrigation is 16.95%.

Table 3.4 Continent-wise Geographical Area, arable land and Irrigated Area - 1989

(Unit - Area in '000 ha)

NAME OF CONTINENT	NO. OF COUNTRIES	GEOGRAPHICAL AREA	ARABLE AREA	IRRIGATED AREA	% OF 4-3	% OF 5-3	% O 5-

To compare the performance of India with the Asian countries, China stands out as the best example with 48.85% of irrigated area of its arable area (see Table 3.5) while India has only 26.03% irrigated area of the arable area. The percentage of arable area to the total geographical area being 9.67% and 50.29% in China and India respectively. Many of the important water basins of the world are shared by more than one country. Common basins make up 60% of the total area of Africa and South America. The importance that nations attach to their water resources is reflected in the existence of treaties relating to common basins.

Table 3.5 Selected Country-wise Geographical Area, Arable Land and Area Irrigated (Unit - Area in '000 ha)

Physiography. climate and land resources of India

India is a country of great geographical diversity. The

variations in its terrain, temperature, rainfall and soils have closely influenced the cropping patterns and other agricultural activities. There are fifteen agro-climate regions in the country (GOI, 1985, P.3). The **North-West mountain region** stretches over the states of Jammu and Kashmir and Himachal Pradesh and the Kumaun and Garhwal divisions (Uttarkhand) of Uttar Pradesh. Agricultural activities in this region are largely confined to the valleys (Kashmiri, Dun, Chamba, etc.), river traces and gentle slopes of the `Kandi' tracts. Rice in the valley floors, and maize in the hilly areas dominate the **kharif** land use. The Suru and Nubra valleys (tributaries of Indus) of Ladakh grow wheat. It is harvested in the month of July and August. The **Northeastern region** sprawls over the seven states, also known as the seven sisters of Northeast India, Arunachal Pradesh, Assam, Manipur, Meghalaya, Mizoram, Nagaland and Tripura. It has two natural divisions : one is the valley of Brahmaputra, and the second is the hilly tracts of the seven states. Rice is the dominant crop in the region. The **Sutlej-Yamuna** plain, is extensively irrigated by canals taken out of the Sutlej, Beas and Yamuna rivers. The greater parts of the states of Punjab and Haryana fall in the Sutlej-Ganga plain. Rice, sugarcane, maize, cotton, fodder and pulses are the major **kharif** (summer) crops while wheat, peas, barley, gram and oilseeds are grown in the **rabi** (winter) season. **The Upper Ganga Plain**, stretches over the greater parts of the Ganga-Yamuna Doab, and Rohilkhand and Lucknow divisions. It is drained by the Ganga river and its tributaries. The region grows rice, sugarcane, maize, pulses and millerts (fodder) in the **kharif** season and wheat, oilseeds, pulses

(grass, lentil), potato and vegetables in the rabi season. The **Middle Ganga Plain** stretches over the eastern Uttar Pradesh and greater parts of Bihar, and north of the Chotanagpur plateau. It forms a transitional region between the upper and the lower Ganga plains. The region is ideally suitable for the cultivation of rice, maize, pulses, sugarcane and a wide variety of vegetables. Wheat, gram, and oilseeds are the dominant rabi crops. The **Lower Ganga plain** covers the lower portion of the West Bengal. Two to three paddy crops in a year is usual practice. **The Southeastern plateau**, covers the whole of Chotanagpur plateau, Baghelkhand and Mahanadi basin. In other words, this region extends from Baster (Madhya Pradesh) in the South-West to Dumka and Salribganj (Bihar) in the North-West. Rice is the dominant **kharif** crop and in the **rabi** season is devoted to gram and lentil. The **Aravalli-Malwa plateau** upland stretches over the Western Madhya Pradesh and the Eastern parts of Rajasthan, and east of the Aravalli mountains. Cotton, soybeans, millets, maize and pulses are the dominating crops in the **Kharif** season, while wheat, oilseeds, gram and lentil are grown in the **Rabi** season. **The Plateau of Maharashtra** stretches over the Western Madhya Pradesh, the whole of Maharastra to the East of the Western Ghats. This region is conducive for the cultivation of cotton, pulses, oilseeds, wheat, grams, and sugarcane. **The Deccan Interior** sprawls over the greater parts of the Karnataka, Andhra Pradesh and Tamilnadu uplands from the Adilabad district in the North to Mudurai district in the South. Millets, ragi, rice, cotton, groundnut and pulses are the dominant crops in the region. **The Eastern Coast** stretches over the entire tract of the Eastern Ghats. It sprawls

from the district of Balasou in the North-East to Kanyakumari in the South. Covered with the alluvial soils deposited by the Mahanadi, Godavari, Krishna, Penna, and Cauveri, it is a humid region. Rice is the leading crop. The Western coast sprawls over the Western fringes of the states of Maharastra, Goa, Karnataka and Kerala. Rice, coconut, coffee, and tea are important crops. The other regions are the Gujarat, Western Rajasthan, Lakshadwipas, and the Islands of Andaman and Nicobar. Thus, the agro-climatic regions have been delineated with a set objective to prepare suitable agricultural strategy for each one of them.

The presence of the great mountain mass formed by the Himalayas and its spurs on the north and the ocean on the south are the two major influences operating on the climate of India with a great diversity and variety of climate, and a variety of weather conditions. The climate ranges from the continental to the oceanic, from extremes of heat to extremes of cold, from extreme aridity and negligible rainfall to excessive humidity and torrential rainfall. It is therefore, safe to avoid any generalization as to the prevalence of any particular kind of climate, not only over the country as a whole but over its major areas (Central Water Commission, 1978, p.222). Thus, the climatic conditions influence, to a great extent, the utilization of the water resources of the country.

Rainfall in India is dependent in differing degrees on the South-West and North-East monsoons,on shallow cyclonic depres-

sions and disturbances and on violent local storms which form in regions where cold and humid winds from the sea meet hot and dry winds from the land and occasionally reach cyclonic dimensions. Most of the rainfall in India takes place under the influence of the South-West monsoon between June and September, except in Tamil Nadu where it is under the influence of the North-East monsoon during October and November. The rainfall in India shows great variations, unequal geographical distribution and frequent departures from the normal. It generally exceeds 1000 m.m in areas to the east of Longitude 78°E. It extends to 2,500 m.m along almost the entire West coast and the Western Ghats and over most of Assam and sub-Himalayan West Bengal. In some parts of the Western Ghats and Assam, the rainfall is as heavy as 6000 to 6750 m.m. In the West of the line joining Porbander to Delhi and thence to Ferozpur, the rainfall diminishes rapidly from 500 m.m to less than 150m.m in the extreme West (see Table 3.6). The Peninsular India has a large area of rainfall less than 600 m.m with pockets of even 500 m.m. per year.

Table 3.6 : Average Annual and Seasonal Rainfall in different Meteorological Sub-divisions of the country (1989-90)

(Unit : Millimeters)

SL.NO.	SUB-DIVISION	ANNUAL AVERAGE RAINFALL	SEASONAL AVERAGE RAINFALL (JUNE-SEPT)

Source : **Report of Annual Rainfall, India; Meteorological Depart ment, New Delhi, 1989-90, p.4**

The highest average annual rainfall areas are the coastal Karnataka, Kerala, Konkan, and the North Eastern states due to South-West monsoon. The lowest average annual rainfall regions are Rajasthan West, Saurastra and Kutch, Haryana, Punjab, Rayalaseema and Interior Karnataka. This shows great variations, unequal seasonal distribution of rainfall, and stregthens the need for the development of water resources in the low rainfall areas. The variations in the rainfall within the state are, however, very considerable while Srikakulam and Vizayanagaram districts received a maximum rainfall of 1250 m.m. Anatapur district in Rayalaseema received only a 544 m.m in a year which is slightly higher than the lowest rainfall in Thar desert in Rajasthan.[1]

The variations in temperature are also marked over the Indian sub-continent. During the winter season from November to February, the temperature decreases from South to North due to the effect of continental winds over most of the country. The mean maximum temperature during the coldest months of December and January varies from 29^{o} C in some parts of the Peninsular to about 18^{o} C in the North, whereas the mean minimum varies from about 24^{o} C in the extreme South to below 5^{o} C in the North. March to May is usually a period of continuous and rapid rise of temperature. The highest temperature occurs in Noth India, particularly in the desert regions of the North-West where the maximum may exceed 48^{o} C. With the advent of the South-West monsoon in June,there is a rapid fall in the maximum temperature in the central portions of the country. The temperature is almost

uniform over the area covering two-thirds of the country which gets copious rain. There is a marked fall in temparature in August and September when the monsoons retreat from North India. The mean maximum In North-West India, is below 10°C. in the month of November. Temperature drops below freezing point In the extreme North, (Central Water Commission, 1978). Thus, variations in the temperature and the direction of the monsoon winds bring different amounts of rain to different climatic regions of India.

Evaporation rates closely follow the climatic seasons and reach their peak in the Summer months of April and May especially in the central areas of the country. With the onset of monsoon,there is a marked fall in the rate of evaporation. The annual potential evaporation ranges between 150 cm. and 250 cm. over most parts of the country. Monthly potential evaporation over the Peninsula increases from 15 cm in December to 40 cm. in May. In the north-east, it varies from 6 cm. in December to 20 cm. in May. It rises to 40 cm. in June in West Rajasthan. After the onset of monsoon potential evaporation decreases generally all over the country. Location, rainfall, nature of terrain, temperature and the availability of irrigation determines the land use pattern of the country.

Table 3.7 : Land-use Classification, 1988

CLASSIFICATION			AREA (in Million Hectares)
A. Area under forest :			67.16
Area not available for cultivation :			
i. Land put to non-agricultural uses :		20.41	
ii. Barren land and uncultivable Land :		20.07	
Other cultivated land including follow land :		31.06	
i. Permanent pastures and other grazing land :		11.93	
ii. Land under misc. tree crops and grows not included in the net sown area :		3.39	
iii. Cultivable waste :		15.74	
B. Fallow land :			24.91
i. Fallow land other than current Fallows :	9.55		
ii. Current fallows :	15.36		
C. Net Area sown :			140.72
D. Total reporting area :			304.72
E. Total cropped area :			175.96
F. Area for which no returns exists :			24.41
G. Total geographical area :			328.73

Source : **Statistical Abstract,** Directorate of Economics and Statistics, Department of Agriculture and co-operation, Ministry of Agriculture, 1988, P.7

Area cropped more than one (175096-140.7) is about 36 million hectares (see Table 3.7).

Only 304.32 m.ha of this total area is accounted for in the latest available land use. Area under forest is 67.16 m.ha. Area not available for cultivation is 40.48 m.ha. Area for which no returns exists is 24.41 m.ha and it largely consists of mountains,deserts and forest and inaccessible areas (Government of India, 1991, pp.1-13). More than 53% of its total area is cultivated. India is endowed with a major viwer system of the world.

Water Resources of Indian ₹ River Basins.

Based on the catchment areas, the river basins of India are broadly divided into three groups. River basins of 20,000 sq.kms catchment area and above constitute the first group which are 14 in number. River basins with catchment area between 2,000 sq.kms to 20,000 sq.kms are classified as medium river basins, and those with catchment area below 2,000 sq.kms are called minor river basins. There is yet another fourth category where a few desert rivers flow for some distance and then are lost in the deserts. Their flow is uncertain (Rao, K.L, 1979, pp.54-89). The inflow into rivers from the plains is estimated to be not much more than 88.3 t.m.c. The bulk of the inflow into the rivers can thus be considered as derived from the upper portions of the river catchments, which lie mostly in India.

Catchment Areas of Rivers :

The reported catchment area of India is 3.05 million Sq.km against the total geographical area of 3.28 million Sq.km. The difference is due to areas for which statistics are not avail-

able[5](see Table 3.8). There is also a difference of 0.16 million Sq.km between the geographical area and aggregate of the catchment areas of all the rivers.

Table - 3.8 Catchment area for the four groups of River systems :

RIVER BASINS	CATCHMENT (m.sq.km)	TOTAL area	RUN OFF (1000 million cubic meters)	RUN OFF (%)	% OF POPULATIO in the basin (
GROUP I Major river basins					
North	1.44				
South	0.72	83	1.406	85	80
Central	0.42				
Total	2.58				
Group II Medium river basins	0.24	8	112	7	
Group III Minor	0.20				20
		9	.127	8	
Group IV Desert rivers	0.10				
Total	3.12	100	1.645	100	100

Source : Rao, K.L. 1979, P.55-56.

The major river basins form 83% of the total drainage area and including the medium river basins they cover practically 91 percent of the total drainage area.

Sources of water supply :

The river basin systems in India and the sources of water supply are significant. Major river basins like Ganga, Indus, Godavari, and Krishna have a number of canals, tanks, and wells (Rao, K.L, 1979, pp.58-59). It is interesting to observe that the storage capacity is the largest in the Ganga basin because of its vast size. Even the Krishna, Godavary and Indus basins have large storage capacity (see Appendix - III-i). Given the assessment that only 38% of our surface flows can be tapped for irrigation purpose, the ultimate irrigation potential from this source would suffice for crop area to the tune of 74 million hectare only. This potential can rise if the exploitable fraction can be enhanced somehow, say due to inter-basin transfer of surplus river waters (Dhawan, 1989). Irrigation schemes in India are usually designed on 75% dependability. There is scope for enlarging our ultimate irrigation potential by constructing irrigating works of low "depndability" as there is an increased relation between dependability and volume of water flow available in a river.

Water Availability:

The average flow in the 20 river systems of the country has been estimated to be 66371 t.m.c[6] (see Appendidix III-ii). But the amount of water that can be actually put to beneficial use is much less due to severe limitations imposed by physiography, topography, inter-state issues and the present state of technology to harness water resources economically (Rao, K.L, 1979,

pp.58-60). There is a big challenge to planners and technologists to tap the available potential water in river basins through irrigation. Conservation of water by storages is important especially in India where the rain water flows into the rivers to the extent of 80% in the four monsoon months (Rao, K.L, 1979, P.57). For the rest of the year, there is only inadequate or no water supply from the rivers (see Appendix-III-iii). Therefore,storage of water is very essential for agriculture in India. It is also necessary for producing power.

Present status of water Resource use :

India will have an estimated population 102 crores by 2007 A.D. With this population and given improvements in consumption levels associated with growth in incomes, the estimated foodgrain requirement for the year 2007 A.D will be around 276 million tonnes. The foodgrain production has to match this level of demand. The required production levels of foodgrains by the year 2007 A.D. will be 282 million tonnes as against 198 million tonnes in 1996-97 (Water Management Forum, 1992, pp.816-844). The required development in agriculture can, in the long run, be achieved only through a regionally broad-based pattern of growth by devoting sufficient facilities of irrigation and maintaining a continuous flow of economically viable and improved techniques.

The ultimate irrigation potential of the country has been estimated to be 113.50 million hectares. It includes 58.50 million hectare from major and medium irrigation schemes, 15

million hectare from surface minor irrigation schemes and 40 million hectare from groundwater exploitation[7]. Irrigation development in India is classified into three categories, viz., major irrigation, having cultivable command area (CCA) of more than 10,000 hectare for each scheme;medium irrigation having CCA more than 2,000 hectares but less than 10,000 hectares for each scheme and minor irrigation, having CCA of 2000 hectares or less for each scheme (Central Water Commission, 1992, P.7). However, the national perspective for water resources development has two components viz, Himalayan rivers development and the Peninsular river development for the inter-basins transfer of waters. It envisages an additional benefits of 25 million hectare by surface water and 10 million hectare by increased use of ground water,which is expected to raise the ultimate irrigation potential from 113.5 million hectare to 148.5 million hectare. Further,the central Ground water Board provisionally puts the revised estimate of ground water at 80 m.ha as against the previous estimate of 40 million hectare.

Out of an average annual flow of 66371 t.m.c, India can develop a live storage of 5185 t.m.c. The irrigated area in the country was only 22.60 million hectare in 1950-51. As compared to this,the cumulative irrigation potential as created upto 1989-90 (the end of VII plan) was 78.12 million hectare (out of which ground water potential was 38.95 m.ha) and the utilization is estimated to be 70.89 m.ha comprising 38.39m.ha from surface water and 32.50 million hectare from ground water. The quantum

of water issued for irrigation these areas would be of the order of 31.12 million hectare of surface water and 12.8 million hectare of ground water(see Table 3.9). The actual utilization up to 7th plan (1989-90) under various uses is just 25% of the total water resources (188 million hectares).

Table 3.9 - Irrigation Uses (Supply of Water) 1990

USES	UTILIZABLE WATER AVAILABILITY (Unit - million hectares)
Irrigation using surface waters	31.12
Irrigation on using ground waters	12.80
Community water supply (Urban and rural area)	2.50
Industrial use	1.50
Energy	0.45
Total	48.37

Source : Central Water Commission, 1992, pp.1-23

The Eighth Five Year plan envisages creating additional irrigation potential of 5.09 million hectare from major and medium irrigation and another of 10.71 million hectares from minor irrigation (Planning Commission, 1992, draft). This would mean that at the end of the Eighth plan (1992-97), 99.19 million hectare of irrigation potential would have been created,out of which 48.14 million hectares would be from surface sources and 51.05 m.ha would be from the use of ground water. The level of foodgrain production by the year 2007 A.D will have to be around 282 mil-

lion tonnes. This has to be viewed against the back drop of the fact that the net sown area being almost stagnant at 140-141 million hectares since 1970-71, and the pressure on land use is increasing due to fast developing industrialization, urbanization etc. The future of increased agricultural production lies with more intensive agriculture, especially by increasing the efficiency of the existing irrigation systems as well as spreading irrigation facilities to other hitherto unirrigated.

The latest estimates indicate that by the year 2000 and 2025, the water use for irrigation will be increased to 63 million hectareand 77 million hectares respectively. The requirement of drinking water is at present only 7% to 10% of the available surface water and 4% of the ground water potential. The country has not yet been able to provide sustainable source of clean drinking to all the people, particularly in rural areas. There are a large number of villages which are only partially covered and a large number of habitations which have no source at all or have inadequate supply of drinking water. It is estimated that 1.5 lakh villages get the drinking water supply less than the one stipulated by norms. Similarly in urban areas also, the 50% of population get the water supply less than the normal.

Against this back drop,it is roughly estimated that by the year 2000 and 2025, the community water supply requirement may go up to about 3.3 million hectares and 5.2 million hectares respectively from the present use of 2.5 million hectare (see Table - 3.10). The industrial demand may also go up to 3 million hectares

and 12 million hectares by the year 2000 and 2025 respectively, from present use of 1.5 million hectares. The total requirement of water in the year 2000 and 2025 would be around 75 million hectares and 105 million hectares respectively.

Table 3.10 : Total Requirement of water (Demand)

Units = million hectares)

	YEAR		
SECTOR	1900	2000	2025
Domestic	2.5	3.3	5.2

Development of Irrigation in India :

There is considerable evidence to show that in ancient India irrigation was practiced extensively. The fact that big cities like Harappa and Mohan-jo-daro were flourishing in the dry areas,points to the existence of extensive irrigation systems in ancient India. In 300 B.C Magasthenes, the famous Greek Ambassador to the court of Emperor Chandra Gupta, recorded that the district officer used to "measure the land and inspect the

sluices by which water is distributed into the branch canals (water sources) so that every one may enjoy his fair share of the benefit" (Rao, K.L, 1979, P.114). Some of these ancient works are found even today. The most famous one, however, is the still functioning Grand Anicut which was built by the Chola rulers in the first century A.D,on the Cauvery. This river divides into two branches,the Cauvery on the right and the Coleroon on the left.In order to prevent the water flowing into the Coleroon branch,which a low level one,the Grand Anicut was constructed to enable the water to pass through the Cauvery and irrigate the fertile Tanjore delta land. Besides this,there are a number of ancient earth dams constructed long ago and still existing[8].

Ferozshah Tughlag (1351-1388) built in the Western Yamuna canal in 1355 A.D to carry the Yamuna waters to his hunting ground at Safidom in Hissar district. Similarly, the Eastern Yamuna canal was constructed during the reign of Emperor Mohammed Shah (1719-1748),Emperor Shahjahan built a canal from the Ravi river through the Shalimar Gardens at Lahore (Rao, K.L, 1979, P.115). But most of the development of the existing irrigation took place during the British regime.

Irrigation works were undertaken during the 19th century principally to overcome the devastating famines that raged in several parts of the country. Two of the most notable British engineers,who did splendid work and built magnificent canal systems, are Proby T. Cautley and Sir Aurther Cotton. Sir Aurther

Cotton constructed the Cauvery delta system. He built a major weir at the head of Srirangam island in 1834 where the Cauvery branches off into the Coleroon and the Cauvery. Sir Aurther Cotton also constructed the Godavari Anicut and the canal system. This diversion system started in 1846 proved the most valuable work in times of drought and famine, irrigating nearby 0.4 million.ha. Similarly, in the Krishna delta, there were a number of scarcities and famines. The weir was branched in 1952, and later was replaced with a barrage just up stream of the anicut and commissioned in 1957. It irrigates about 0.5 m.ha. Cautley began the construction work on the upper Ganga canal in 1836 and completed it in 1854.

In the latter part of the 19th century the important irrigation works constructed were the Sir Hind canal, the lower Sohang and Para canals,the lower Chenab canal in Punjab and the lower Ganga canal, the Agra canal, the Betwa canal in Uttar Pradesh, the periyar system of canals in Tamilnadu, the Mutha canals in Maharastra (Rao, K.L., 1979, P.116). Irrigation works in the 20th century witnessed an important event in India's history,namely the appointment of the Irrigation Commission. The Commission toured the country extensively and based on its findings submitted its report in 1903 (Government of India, 1903, P.66-68). It states that, as regards new works,the main question is not whether they will be likely to prove directly remunerative, but whether the net financial burden which they may impose on the state in the form of charges for interest and maintenance

will be too high a price to pay for the protection against famine.

Important projects undertaken in the country were the Tribeni canal project in Bihar,the Pravara canals,the Godavari canals,the Nira Right Bank canals in Maharastra,the Sarada canal project in U.P and the Weinganga and the Mahanadi canals in Madhya Pradesh. Between 1921 and 1935, a number of notable irrigation works were constructed,among them being the Krishnaraja sagar project in Karnataka, the Nizamsagar project in Telengana (Andhra Pradesh) and the Mettur project in Tamil Nadu. In 1935,after the passing of the Government of India Act, irrigation was transferred from the control of the central Government to that of the respective provincial or state Governments (Central Water Commission, 1978, P.6-7). This made a significant change into governing irrigation projects and their administration,as irrigation became a state subject and central Government was concerned only when disputes arose between the neighbouring states.

It is really in the second half of the century that the gigantic projects were built. The First Five Year Plan emphasised on irrigation and agriculture. However, much effort was not made in the irrigation front. The emphasis in the Second Plan was on irrigation along with industry. It was from the Third Plan onwards that adequate emphasis was laid on the development of irrigation in the country. Till the end of the Seventh Plan

(1985-90),an amount of Rs. 45191.49 crores has been spent, of which Rs. 26,133 crore has been spent on major and medium projects (see Table 3.11). The remaining amount has been spent on minor irrigation,command area development and flood control.

Table - 3.11 Magnitude and Composition of Investment on irrigation and Flood Control in the Plans (1950-1990).

Source : **The Eighth five Year Plan (1992-97)** May, 1992, P.51

In the pre-plan period, the potential and utilization of the major and medium irrigation systems was 9.70 m.ha. The minor irrigation sources was 12.90 m.ha. The Gross irrigation areas as per land utilization statistics was 22.56 m.ha. From the first plan onwards, development of irrigation has been taking place. The potential and utilization of major and medium irrigation systems at the end of Seventh Plan were 31.52 m.ha. and 27.77 m.ha. and the minor irrigation potential and utilization were 46.83 m.ha and 43.53 m.ha respectively (see Table - 3.12). This indicates that there is a considerable gap between the potential and utilization.

Table - 3.12 Development of Irrigation Potential through in the Plans (1950-1991)

Source : **Report of Working Group on Eighth Five Year Year Plan on Ma and Medium irrigation, Minor Irrigation.** Government of India, Planning Commission, 1992, p.5.

Since inception of the First Five Year Plan up to the end of the Seventh,an amount of Rs.45,191.49 crores has been spent on major, medium and minor irrigation (see table 3-12). The Command Area Development Agency (CADA) and flood control and the potential created is 446.85 million ha. The expenditure during the above period on irrigation alone was Rs.42,762.45 crores.

Position of the States in India :

Andhra Pradesh occupies sixth place in the Seventh Plan as far as allocation is concerned (see Table 2.12). As regard the ultimate irrigation potential,a few states like Haryana and West Bengal will exceed the ultimate irrigation potential by 147.61% and 158.17% respectively. Andhra Pradesh when compared to these states,is far behind to achieve targeted ultimate irrigation potential. Unequal distribution of water across canal command in its different reaches, the losses in conveyance and field applications under each type of systems are much higher actually than what are assumed, the physical control devices are inadequate and crude.

Irrigation Development in Andhra Pradesh

The economy of Andhra Pradesh is largely dependent on agriculture. The state is rightly called 'a River State' as it is blessed with major River systems like the Godavari, the Krishna and the Pennar and 37 others[9]. Thus,the state is blessed with a vast scope of developing irrigation potential (Andhra Pradesh at

50, 1998, PP.1-10). The state has a mean annual rainfall of 858 m.m and about 670 m.m or 78% of the total rainfall contributed by South- West monsoon.[10]

The state has a geographical area of 275.07 lakh ha. and a population about 683 lakhs. The net area irrigated in the state is around 44.7 lakhs ha. representing 40.6% of total irrigated area as per 1988-89 Agricultural census. The total surface water from the entire river systems of the state is estimated to be in the order of 7.7710 m.c.m (2,746 t.m.c) at 75% dependability (**Andhra Pradesh at 50,** 1998, pp.1-10). The ultimate irrigation potential is assessed in 87.80 lakhs ha. under major and medium and minor irrigation projects including 23.00 lakhs ha. under surface water major irrigation schemes.

The physical features of the river systems, the soil, the rainfall and the climatic conditions are suitable for agriculture and the pattern of crops is dependent on the agro-practices, dating back to times immemorial. Around 81% of the population is by and large dependent on agriculture and other allied occupations. This leads to the logical conclusions that the socio-economic development is dependent on the creation of irrigation facilities considering the historical background age old know-how of the agriculture of water and land resources. This encourages establishment of agro-based industries and helps in the all round development of the State's economy.

Table 3.13 THE STATE-WISE PERFORMANCE IN THE VII PLAN

STATE	ALLOCATION (RS. IN LAKHS)
Gujarat	1,46,909
Uttar Pradesh	1,42,000
Madhya Pradesh	1,37,592
Maharashtra	1,32,000
Bihar	1,28,580
Andhra Pradesh	1,18,230

Irrigation Sources and their utilization in Andhra Pradesh :

Many irrigation projects were constructed during the last century and the pre-Independence period. Some of the major works are the Krishna delta canals, the Godavari delta canals, the Pennar system, the Nagavali, Vamsadhara schemes (see Table-3.14). The Godvari and Krishna,and the Tungabhadra the three inter state rivers,and the Penna and 37 other meduim and minor river systems are estimated to carry a total dependable annual yield of 0.2746 T.m.c, (i.e,7.771 million cubic metres) (see Table 3.14). The irrigation potential created before the pre-plan period under major and medium irrigation was 16.76 lakh ha.

Table - 3.14 Water Resources in Andhra Pradesh

RIVER SYSTEMS	DRAINGAGE AREA IN THE STATE IN THOUSAND km2	% OF DRAINAGE AREA TO THE TOTAL AREA OF THE STATE	ASSESSED ANNUAL YIELD IN STATE IN (MILLION CUBIC METERS)
Godavari	73.201	26.45	4.2308

The ultimate irrigation potential contemplated from the major and medium schemes for the state as a whole has been assessed as 64.80 lakh.ha. The total potential created from the projects of

pre-plan schemes and the projects extended during the First to Seventh Plan is 33.49 lakh hectares and the potantial created from minor irrigation is 18.34 lakh hectares (see Table 3.15). Their total expenditure amounts to Rs.3215.85 crores. (Government of India, 1992, P.9). The plan efforts of Andhra Pradesh has been so far based on the strategy which had laid emphasis on building up the basic infrastructure both for agriculture and industrial development viz., development irrigation and power.

Conclusion:

The world consists of one-third land and two-thirds water. The water resources in this one third land consists of surface and ground-water. Fresh water for human use. found in lakes, swamps, and rivers makes up only 0.008% of the Earth's water. This shows the scarcity of the usable fresh water. Globally, most water is used for agriculture (about 69%). This reveals the importance of irrigation development which consumes large amount of fresh water. India is a country of great geographical diversity. There are fifteen agro-climatic regions in the country. Andhra Pradesh region stretches over the Deccan interior and Eastern coast covered with alluvial soils deposited by the Mahanadi, Godavari, Krishna and Pennar. The river basin systems in India and the sources of water supply are significant. These basins have large storage capacity. Given the assessment that only 3.8% of our surface flows can be tapped for irrigation purpose.

The future of increased agricultural production lies with more intensive agriculture, especially by increasing the efficiency of the existing irrigation systems as well as spreading irrigation facilities to other hitherto unirrigated.

The gap between the potential created and utilized and the lag between them is the first of the efficiency related problems. This is attributed to many reasons ; the delays in the extension of the canal systems during which the farmers in the upper reaches raised more water intensive crops like rice,the inability of farmers to invest in land development and field channels and deficiencies in the structures. The second relates to the inefficient, wasteful and harmful use of water. The traditional method of over flow of water from one field to next results in use of more water than required for a crop, raising crops with higher requirement of water with the resultant problems of wastage,water logging and salinity. The third relates to the most common conflict occurs between upstream users who claim sovereign rights to that originates or flows through their territory (including right to use, store, direct or pollute) and water course be maintained in its natural state. Given the constraints of public financial resources and the demand for irrigation out pacing its growth, there have been too many projects competing for the few resources, a thin spread thereof with the consequence of time and cost overruns. These aspects of inefficiencies led to the realisation of the need for optimising output per unit of water per unit of crop land per unit of time through efficient management of available water resources.

Sources : **Statistical Directorate, Central Water Commission, Water an Related Statistics**, April, 1992.

NOTES :

1. India being a country of continental size, the annual rainfall, which is the ultimate source of both surface water and ground water, is variable across its land mass. While peninsular and North-Western India have large areas of about 1150 mm. few states in the far eastern India and the narrow strip of western coast (Konkan down to Malabar) have more than twice the national average. Thus the picture of abundance of water is confined mainly to these high rainfall traits (Dhawan, B.D., 1989, P.20).

2. Roughly 97% of the Earth's water resources are in the oceans and are saline. Only 2.5% of the world's water is fresh water and of that a mere fraction is available to man (Keller, R. 1984, pp.7-24).

3. The amount of water stored in the global hydrosphere is three orders of magnitude larger than the annual precipitation. Total fresh water and slain water (including water vapor) in the hydrosphere is estimated at 1,454 million km^3. If the total 4.4 million km^3 of fresh water, approximately 60 million km^3 is ground water, 24 million km^3 is in the sheets, 280,000km^3 is in lakes and reserviours, 85,000 km^3 is in soil moisture, only 1,200 km^3 is in rivers, and only 14,000 km^3 is in the atmosphere at any time. This means that the entire amount of stored atmospheric moisture is recycled every ten days, and the storage in rivers is changed every eleven days Robert, (ed.,) 1986, op.cit., pp.255-

4. In many countries the agricultural demand for water dominates the total demand. Hence, small changes in the agricultural demand can free large quantities of water for other uses. It is important that irrigation water be used efficiently (Repetto, pp.255-298).

5. The mean flow in the Brahmaputra and Barak rivers of the east amounts to about 59 million hectare - metres (MH M), about one-third of the combined flow of all the Indian rivers put together. As hardly 5% of this flow is exploitable as per the present expert assessment. This brings down the overall utilisability of the Himalayan flows to 32%. Likewise, the exploitability of the short, coastal rivers originating from the high rainfall mountains of the Western Ghats is quite low, namely 16%. Thus the rivers, which are very beautiful because of either high rain or snow preciptetation in their catchments (Himalayan and Western coastal rivers of the Western Ghats) have utilisable flows to the extent of about 1/4 only. On the other hand, the less beautiful rivers of the peninsular India, because of the rocky terrain through which they flow, have comparatively high proportion of utilisable water (Dhawan, B.D, 1989, **op.cit.**, pp.17-25.

6. Bansil had given the water resources of India by river basins that the average annual flow of all river basins in India was 178.0 million hectare metres, while utilisable flow was 70 million hectare metres (Bansil, P.C. 1990, P.227).

7. Bansil presented data on irrigation potential of major and medium projects in India as 40.47 million hectares (Bansil, P.C. 1990, op.cit.,pp.223-229.

8. The principal masonry work undertakes during the native period is the unknown as the Grand Anicut, re-built in the eleventh century, and situated just below the island of Shreerungam, where the Cauvery and coleroon come into close contact with each other. At this point the bed of the coleroon is nine or ten feet lower than that of the Cauvery and the Grand Anicut was therefore built across a outlet of the Cauvery to prevent its water being wholly drained off into Coleroon. These works were beneficial, but did not check in any way the evil resulting from the unequal distribution of the volume between the two main streams. In 1836, under the advice of Sir Aurther Cotton, the upper Coleroon anicut was built across the head of the Coleroon branch, and was completely successful in its object of throwing into the cauvery branch a fair distribution of the water supply by the simple expedient of placing the crest of the anicut at such a height as to ensure, in the average state of the river, a proper distribution of the entire volume of the mainstream between the two branches during the irrigation season. In 1848, the construction of a regulating dam to the first principal offshoot from the Cauvery branch was began and subsequently regulating dams were provided for the other principal branches, thus completing the general system of regulation and control of the water required for the delta irrigation (Maclean, C.D., 1987, pp.339-340.)

9. The data show the extent to which this is an irrigating state.

The major irrigation development have been taken place since British regime. In 1844-45 the Godavari Anicut was built across the river which served the area 6,13,518 acres (1882-83). Another major anicuts were the Kistna (1852), the Pennair (1853-1855) the K.C. Canal (1858) which served the area 2,86,613 acres, 2,24,969 acres and 72,358 acres respectively as on 1882-83. Maclean, C.D., 1987 ; op.cit., pp.387-420).

10. Bansil presented data on minimum and maximum water storage in reserviours in 1985 of Andhra Pradesh were namely Nagarjunasagar (minimum 0.881 tm. cum and maximum 5.504 tm. cum), Sriramsagar (minimum (-) 0.120 tm. cum and maximum 0.777 tm. cum) and Srisailam (minim 1.188 tm. cum and maximum 8.273 tm. cum) respectively (Bansil, P.C, 1990, op.cit., pp.223-229).

CHAPTER - IV

INVESTMENT IN MAJOR AND MEDIUM IRRIGATION SCHEMES

Introduction:

The term investment is most commonly used to describe the flow of expenditures devoted to increasing or maintaining the real capital stock. Investment, in essence, is the present sacrifice for future benefit. But the present is relatively known, whereas the future is always an enigma. Investment is also, therefore, sacrifice for uncertain benefit (Hirshleifer, J, 1965, P.1). In other words, investment is the flow of expenditures devoted to the projects producing goods which are not intended for immediate consumption. Also investment means an addition to the supply of facilities provided to satisfy certain demand. Supply implies cost of both construction (or first cost), and operation and maintenance cost to keep the facility running. Demand implies that someone receives some satisfaction from the investment and its upkeep (Henry Malcolm Steiner, 1980, P.2). Thus pattern of investment involves process of innovation, that reduces the cost per unit of output [1] (Sukchamoy Chakravarty, 1982, P.35). Investment is a flow, the volume of an intended rate of return greater than the interest rate.

Theory of Investment:

At the heart of investment theory lie some empirical facts. The price of an installed investment good i.e., demand price, market price or shadow price of an investment good differs from the price of a newly produced investment good supply price, replacement cost or reproduction cost (Marcel Savioz, 1992, P.3). When the demand price of an installed investment good is higher than the supply price of a newly produced one, this would instaneously be followed by a large increase of production and installation of investment goods, so that these prices would almost instantaneously be brought to equality. But this is precisely not the case. The main problem of investment theory is thus to provide a theoretical explanation for the sluggish adjustment of these to prices to one-another .

Three types of investment models can be distinguished, with regard to the theoretical explanation they provide for the sluggish adjustment (Marcel Savioz, 1992, pp.4-8). One is the time to build model. It assumes that there is a lag between the time when the firm buys an investment good and the time when the investment good becomes productive. This lag, called time to build, is due to the installation process. It assumes that relative prices change so that it becomes profitable to the firm to increase its capital stock. If the change is expected, the firm, taking the time to build lag into account, will advance its order for new investment goods and the actual and desired capital stock will not differ. On the other hand, if the change is unexpected,

the short-run supply of productive investment goods being inelastic, i.e., determined by past investment decisions because of the time to build lag), the desired capital stock will differ from the actual capital stock. So also will the market value of investment goods differ from their reproduction value.

The second type of investment model is adjustment costs model it assumes that investment goods are only productive after being installed and that the installation process is costly. The installation costs are assumed to be convex (Marcel Souioz, 1992, pp.4-8). Therefore, a "quick" adjustment of the actual capital stock to the desired capital stock is more costly than a "slow" adjustment.

Lastly, Non-Walrasian models assume that the markets like the investment goods market not only generate "price signals" but also quantity signals. such a quantity signal exists in the investment good market if an upper limit to the quantity of investment goods that a firm can purchase exists, and if this constraint is binding (Marcel Souiz, 1992, pp.4-8). Interesting-ly, it can be shown that the mere expectation that the constraint will become binding in the future (an expected quantity signal) is sufficient to bring about a divergence of the market value of investment goods from their replacement costs. This in turn activates the demand for investment goods.

None of the three approaches is fully satisfactory. The lag postulated in time to build model is technically given and is

independent of the relative prices. This means that however strong the pressure for a quick adjustment of the actual capital stock to the desired capital stock may be (e.g., if the market value happened to be a multiple of the reproduction cost), these models assume that there is no incentive for the firms to shorten the time to build lag.

Adjustment costs models suffer from a quite similar weakness. They assume a long-run inelastic supply of investment goods. This means that these models unrealistically assume that no resources can be engaged to ease the installation process and thus decrease the adjustment costs, even if there would be sufficient time to do so.

Non-Walrasian models are even less satisfactory. First, they presuppose arbitrary the rigidity of at least one nominal price and provide no explanation for this nominal rigidity. The second and more striking fact is that while time to build and adjustment costs models of investment try to establish the theory of investment some intrinsic characteristics of investment goods, this is not the case in Non-Walrasian investment models.

Most "classical" investment models can be recast within the "adjustment costs approach". This approach thus provides an integrative framework for investment theory (Junankar, 1972, pp.3-7). The 'Keynesian approach' tackles this problem by introducing supply constraints in the industry supplying capital goods which then determine the aggregate realised investment. This

method does not provide a determinate micro investment function (referring to the firm), nor does it provide an investment demand function (i.e., a function for planned investment). The `post-Keynesian approach' discuses various accelerator theories which assume that the first is cost minimizing rather than profit maximizing and thus derive investment functions. `Neo-Keynesian approach' provides a determinate planned micro investment function. It does this by introducing a cost Of adjustment function which makes it more expensive at the margin to adjust rapidly. The firm then chooses an optimizing path, given the adjustment costs, which takes it to its long-run equilibrium position. The `neo-classical' approach is concerned with a completely different problem, which is one of comparative dynamics. This approach used marginal analysis to analyse the pricing of goods, services and factors of production in competitive markets. They emphasised that the market prices of goods and factors were related to their scarcity.

The above approaches reveal that investment demand theory requires both the flow and stock approaches. This is so because the demand price of an investment good is nothing but the present value of the present and future nominal product of capital. When applied to concrete situations these theoretical issues present economic problems which influence both public and private investments. Public investments are largely infrastructural in nature. The private sector investments are normally analysed from the private point of view. They accept the working of the price system as a proper indicator of costs and benefits. Public

sector investments, since they are made from the view point of the society as a whole, sometimes require adjustments to the prices indicated by the price system. In addition, public sector projects are usually subject to some sort of political judgement.

None of these theories can fully explain the behaviour of private investment. Taken together, they emphasize all its major determinants. In a developing economy, investment is also influenced by other economic and non-economic variables. This is mainly because in many a developing country like India, government plays a very important economic role under the mixed economic principles and national economic plans that have come to be the order of the day, and government's policies and programmes vitally affect economic activities in the country. That is to say, in a less-developed economy, government investment has to assume a dominant role in the process of industrialization. Infrastructural public investment (eg. irrigation, power, and transport,) increases the production potential of private sector to the extent the entrepreneurs take advantage of these social overheads[2].

Special considerations of investment criteria in developing countries are also necessary because markets are so imperfect that many market prices of both commodities and labour are greatly out of line with social opportunity costs or shadow prices, i.e., to evaluate public sector investments through consideration of the opportunity cost to society of diverting resources from marginal private sector projects to public sector ones for

dealing with welfare of the people. Use of market values may give wrong indications of the relative social values of goods and factors of production and lead to a misallocation of resources especially in irrigation sector in India, where irrigation sector is largely funded by government through budgetary allocation, owing to its high cost nature and to achieve certain social goals.

A major determinant of growth in area irrigated by surface irrigation is the volume of public investment in such projects. Annual expenditure in real terms and per hectare of irrigation potential created rose steadily throughout the period of time (Leslie Abbie, **et.al.,** 1982, P.5). The rise in real expenditure per hectare of irrigation potential created is the result of three forces : a progressive increase in the number of projects under construction, meaning an increasing proportion of funds are spent on the early stages of projects, before they begin yielding benefits; a proportional shift to more difficult and high cost projects as the easier and cheaper opportunities for irrigation development were used up ; and improved standards of design and construction in order to capture greater agricultural benefits.

As irrigation development in India has progressed over the decades, several problems have come up to the forefront. They are the problem of paucity of funds which not only restricts the taking up of new projects, but also puts severe restrictions on operation and maintenance of the existing surface irrigation systems and the completion of the ongoing and unfinished pro-

jects. Another problem is the poor performance, specially of the existing major and medium irrigation systems[3]. This problem is largely a fallout of the first, but that would be too simplistic an explanation. Even though adequate investible resources and working expenses are essential requirements of the management of the systems created, increased resources devoted to operation and maintenance alone cannot bring about desired changes in the efficiency of the systems.

Large-scale irrigation is synonymous with canal irrigation in India. This category of works have some salient features. These are in the public sector; they tap river flows with the help of barrages and large dams built across the rivers; the cultivable command area of any major irrigation project is above 10,000 hectares; and that of a medium irrigation work is between 2000 and 10,000 hectares (Central Water Commission, 1991, P.4). Such large systems involved high cost of construction, but the returns are too low to allow for any expansion.

INFLATIONARY NATURE OF IRRIGATION INVESTMENT:

Inflation means a sustained rise in the general price level. It is the proportionate rate of increase in the general price level per unit of time. This phenomenon is arising from an autonomous rise in costs. While one should look into the question of the increasing costs of construction, repairs and maintenance of irrigation sources, it is obvious that the costs of these items are bound to increase over time in an inflationary

economy where the prices tend to increase year after year, continuously. With economic development and improving standards of life, labour cost and cost of materials (cement, iron and steel and machinary and transport exquipment) also tend to increase contributing to rising cost of construction, repairs and maintenance[4]. The data show that wholesale prices of all commodities including food and non-food items, manufactured products have increased 8 times in the country between 1939 and upto 1970-71 at 1939-40 prices. This had further increased to 3 times at 1970-71 prices upto 1983-84 and 2 times at 1980-81 prices upto 1990-91 (see Table 4.1). This has obvious effect on the cost of construction, repairs and maintenance of irrigation sources. Thus costs have been increasing over time in purely monetary terms.

TABLE - 4.1 INDICES OF WHOLESALE PRICES (ALL COMMODITIES) IN INDIA

YEAR	WHOLESALE PRICES INDEX

IRRIGATION INVESTMENT IN THE MADRAS PRESIDENCY:

Irrigation works could be classified in order of technical complexity as diversion works, storage schemes and multi-purpose river schemes. In monetary terms, the cost of all the three categories have been going up. However, the works in the Madras Presidency classed under productive public works upto the end of 1883-84 were the Godavary delta in Godavary district, the Kistna delta in Kistna district, the Kunrool-Cuddapah canal in Kurnool and Cuddapah districts, the Nellore and Sangam **anicuts** in Nellore district, Baroor tank in Salem district, Cauvery delta in Tanjore district and Shreeuicoontam anicut in Tirneully district. They come under productive works. The capital expenditure per-acre irrigated from the commencement of the works upto the end of 1882-83, and the maintenance charges debited to revenue during the year 1982-83 for all works for which capital and revenue accounts were kept audited (see Table - 4.2). The capital cost of Kurnool-Cuddapah canal, in proportion to its inrrigated area, far exceeded that of any other work, and the capital expenditure on the Palandoray **anicut** and Madras water supply works was disproportionately high as compared with the remaining works. The cost of maintenance of Kurnool canal was abnormally high owing to the serious accidents the works had received (Atchi Reddy, 1995, pp.116-118). It is unfortunate that the failure of this major project had discouraged for ever the private investment in the major projects in India.

TABLE - 4.2 THE AVERAGE COST OF CONSTRUCTION AND MAINTENANCE OF WORKS FOR WHICH CAPITAL AND REVENUE ACCOUNTS ARE KEPT (PRODUCTIVE PUBLIC WORKS, 1883-84.

	ANNUAL EXPENDITURE PER ACRE	
	CAPITAL ACCOUNT TO END OF 1882-83 (RS.)	REVENUE ACCOUNT DURING 1982-83 (RS.)
Godavary Delta	18.23	0.64
Kistna Delta	22.50	1.06
Pennair Anicut	22.45	0.72
Kurnool canal	1189.36	8.95
Cauvery Delta	1.17	0.35
Shreeuicoontam Anicut	63.34	1.48
Palandoray Anicut	104.41	15.77

Source : C.D. Maclean Report, 1987, Vol.I, P.419.

Among the diversion works, storage schemes and multi-purpose river schemes, the last two were inherently costier than the first (see Table 4.2). Irrigation works during the British periodwere mostly diversion works across rivers and streams. Ideal sites were used for construction of cheap diversion works in the British period making it obligatory in the recent years to go in for talking of more complicated sites upstream for locating high dams capable of storing large quantities of water.

INCREASING COST OF IRRIGATION IN INDEPENDENT INDIA:

Investment in irrigation started during the British era, although it was only in the post-Independent period that a concentrated effort was made in developing irrigation networks on a major scale. During the last 40 years of 1951-90 as much as Rs.262.22 billion (at historical prices unadjusted for inflation) has been spent by the country on the development of major and medium irrigation schemes (GOI, 1989, pp.1-108). This investment increased the irrigation potential by 22.14 million hactares, from a pre-plan (1951) level of 8.62 million hactares to 30.76 million hactares by the end of the Seventh Plan. However, many of the relatively cheap schemes required for developing irrigation in areas with comparatively easy access to water were more or less exhausted during the British period. The states of Andhra Pradesh, Tamilnadu and Uttar Pradesh witnessed the development of a large number of major irrigation schemes during the pre-Independence period. By the time the Independent government of India took up construction of irrigation schemes with the beginning of the plan-period, the capital cost of building up such schemes had increased substantially (see Table 4.3). The working group on major and medium irrigation for the Eighth Plan (1990-95) found that at current prices, investment in irrigation had increased from Rs.1,530 per hectare of irrigated area in the First Plan to Rs.34,924 in the Sixth Plan and to more than Rs.36,800 in the Seventh Plan.[5]

Various factors have contributed to this escalation in cost from the late 1970s. A large number of new projects were taken up in most states(see Table 4.4), during the Fifth Plan (1974-78). As many as 404 major and medium irrigation schemes were taken up in the Fifth Plan as compared to only 127 in the Fourth Plan.[6] This sudden increase in the number of projects undertaken resulted in their spreading of the limited funds available for irrigation investment. substantial sums continued to be invested, in the aggregate, but in many cases produced no output for long periods of time because funds were divided among many uncompleted projects.

TABLE - 4.4 : NEW SCHEMES WERE TAKEN UP IN DIFFERENT PLANS

PLANT PERIOD	NO. OF SCHEMES
First Plan (1951-56	236
Second Plan (1956-61)	139
Third Plan (1961-66)	101
Annual Plans (1966-69)	48
Fourth Plan (1969-74)	127
Fifth Plan (1974-78)	404
Annual Plan (1978-80)	68
Sixth Plan (1980-85)	182
Seventh Plan (1985-90)	47

Source : **Government of India**, 1990-95, pp.1-108.

Secondly, projects taken up in the later plans are often on relatively different terrain and involved more geo-technical problems and entailed higher costs. In addition, environmental and rehabilitation considerations which were of little or no consequence for projects taken up earlier, are now an integral and substantial part of the capital outlay of any irrigation scheme. thus, in short, rising prices, wages and cost of materi-

als contribute to rising costs of construction, repairs and maintenance.

TABLE - 4.3 CAPITAL COST OF MAJOR AND MDEIUM SCHEME DEVELOPMENT PLANNING COMMISSION ESTIMATES

PLAN PERIOD	EXPENDITURE (B RS.) AT 70-71 ACTUAL PRICES		POTENTIAL CREATED (M.Ha)		APPARENT INVESTMENT (RS.) PER Ha. OF POTENTIAL CREATED AT 1970-7 ACTUAL PRICES	
		ANNUAL AVERAGE	PLAN-WISE	ANNUAL AVERAGE		
1	2	3	4	5	6	7(=2/5)	8(=3/5
First Plan(1951-56)	3.80	8.27	1.65	2.48	0.50	1,530	3,340

Source : **Report of the Working Group on Major and Medium Irrigation Programme for the eigth Plan**, 1990-95, (Government of India, 1989).

Expenditure at 1970-71 prices (column 3) are taken from the Report of the Working Group on Major and Medium Irrigation Programme for the Eighth Plan (1990-95) (p.II-10). It does not explain what sort of deflator it uses to convert yearwise expenditures at 1970-71 constant prices. Instead, it gives the source of the deflator as Perspective Planning division in Planning Commission. Enquiries with PPD revealed that they had worked out only an overall GDP deflator, and not the one specific to irrigation costs of major and medium irrigation schemes.

The figures in column 4 are annual averages of real expenditure (at 1970-71 prices) incurred on major and medium schemes within the relevant plan.

The figures of irrigation potential created in theSixth Plan (2.11 M.Ha) is the reassessed one, which is about 38 percent lower than the one relased earlier (3.40 M.ha).

INCREASING COST OF IRRIGATION IN ANDHRA PRADESH:

The increased in real cost due to complexities of construction of the modern reservoirs with high dams, the average per hectare costs of construction of different types of irrigation works executed in Andhra Pradesh over time had increased (see Table 4.5). It is interesting to note that the average cost of creation of potential for an hectare from the Godavary Delta system was just Rs.62 in 1890. The cost of Rs.1418 per hectare in respect of Kurnool-Cuddapah canal in 1870 was considered abnormal so far as the period is concerned (see Appendix-VI).

The average per cost in respect of 22 works executed upto the end of 1900 A.D. in the century worked out to a mere Rs.84 whereas for the State of Andhra Pradesh the average per hectare cost of the 3 delta systems excluding Kurnool - Cuddapah canal worked out to just Rs.111. During the plan period (1951-95) as much as Rs.54,044 million (at historical prices unadjusted for inflation) has been spent by the state on the development of major and medium irrigation schemes. This investment increased the irriga-

tion potential by 2,335 thousand hectares, from a pre-plan (1951) level of 1,331.0 thousand hectares to 3,666 thousand hectares by the end of the Eighth Plan (1990-95) found that current prices, investment in irrigation had increased from Rs.4,870 per-hectare of irrigated area in the first Plan to Rs.40,682 in the Eighth Plan (see Table 4.6). Various factors have contributed to this escalation in cost from the late 1970s, the major chief reasons being time and cost over-runs and spill over projects. These factors are same when comared to India as a whole.

TABLE - 4.5 SHOWING COST PER ACRE UNDER ANNUAL IRRIGATION FROM DIVERSION WIERS (1988-89 PRICE LEVEL)

NAME OF THE PROJECT	ACTUAL ESTIMA-MATED COST (RS. LAKHS)	TOTAL AREA IRRIGATED OR TO BE IRRIGA-TED (HECTARES) (1960-61)	COST OF PROJECT PER HECTARE OF AREA IRRIGATED (RS.)	YEAR OF COMMEN-MENT	YEAR OF COMPLE TION

TIME AND COST OVER-RUNS :

The surface water potential available for irrigation and other purposes in India is at 2740 thousand million cubic feet (TMC) for creating an irrigation potential of about 210 lakh acres, out of which 158 lakh acres including Rs.41.40 lakh acres under pre-plan schemes and 30.75 lakh acres under the plan projects (1951 to 1985), were for the major and medium irrigation projects working out to 35.77% of available area for cultivation (GOI, 1984-85; pp.105-126). Talking of resources, one has to take note of the escalating cost of irrigation projects and consequent delays in their completion. The larger inequity of the beneficiaries from irrigation passing on the cost of maintenance of the sources and the cost of servicing the debt incurred to benefit them to the general tax payer has continued. The constraint of public financial resources, low recovery from irrigation sector, the demand for irrigation out pacing its growth, too many projects competing for the few resources, were the reasons for time and cost over-runs.

SPILLED-OVER PROJECTS :

The Sixth Plan (1980-85) envisaged an outlay of Rs.747.30 crores (24.11 percent of total plan outlay) comprising Rs.658.30 crores on the 41 on-going projects (10 major and 31 medium and Rs.89 crores on the 20 new projects (6 major and 14 medium) for creation of an additional irrigation potential of 12844 thousand acres (GOI, 1984-85; P.105-126) also (see Table-4.7).

TABLE 4.7 SPILLED OVER PROJECTS - PLAN PERIOD (1951-85)

ITEM	MAJOR	MEDIUM	TOTAL
Total No. of Projects taken up to March 1980	16	71	87
Number of projects completed up to March, 1980	6	40	46
Number of projects spilled over to Sixth Plan	10	31	41

Source : **"Report of Comptroller and Auditor General of India"**, Work expenditures : Financial results of Major and Medium Irrigation schemes, 1984-85, pp.105-126.

The other reasons for time and cost over runs in the programme of completion of these projects along with the cost of construction, repairs and maintenance were mainly due to taking up of additional items of work not contemplated in the original estimate. Cost escalations, insufficiency of funds, procedural delays in land acquisition, stoppage of works by contractors, foundation problems, change in scope an design of works, non-receipts of clearance from government of India for de-reservation of forest area and non-completion of bridges on railways crossings or other reasons (See Table - 4.8). According to latest estimates (Audit Report, 1984-85) substantial investments of

Rs.1448.53 crores for the remaining 39 on going projects and Rs.2907.07 crore for the 7 new projects taken up during the sixth plan period were required for their completion.

TABLE - 4.8 COST INCURRED DUE TO DIFFERENT REASONS

REASON	COST (Rs. in crores)
1. Price escalation	372.84
2. Change in Design and additional works	794.38
3. Inadequate provisions	145.80
4. Inadequate survey and investigation	52.00
5. Other reasons	887.80
Total	1452.82

OPERATION AND MAINTENANCE COSTS OF MAJOR AND MEDIUM IRRIGATION WORKS IN INDIA :

Effective operation and maintenance of the existing system is generally presumed to be one of the important determinants of the degree of utilization of the created potential and efficient use of water resources for irrigation. The gap between the created potential and its utilization has been increasing steadi-

ly, specially in respect of major and medium canal irrigation systems in Andhra Pradesh and this has been a matter of concern during the eighties and nineties. The operation and maintenance of the public surface irrigation systems (major and medium) are largely carried out by the government. The responsibility of the state irrigation departments lies in maintaining facilities and regulating water supply up to outlets which commands any where between 12 to 100 acres (Gulati, et al., 1994; P.2). There are instances where the irrigation departments are found maintaining the structure below the out-let level also, say field channels etc. There are, however, instances of the user's involvement in maintenance of the tertiary systems and below. The need for attending to and maintaining the physical structure which comprises irrigation system arises from the normal wear and tear which these structures and facilities are subjected to. These physical facilities are expected to give service over the entire life of the project, maintaining the efficiency of the system through periodic repair and maintenance is a pre-requisite.

Apart from the main canal and its components, a number of branches, distributaries, minors and sub-minors taking off from the main canals, also have to be maintained. The department, concerned, is also required to construct and maintain an elaborate communication network and support infrastructure. Some of the hydraulic and engineering components of irrigation schemes such as embankments and gates need more regular maintenance and repair than others owing to the frequent damages caused to them. Therefore, special attention has to be focussed on them.

There are four components of the expenditure on operation and maintenances costs. : (i) Direction and Administration, (ii) Machinery and Equipment, (iii) Extension and Improvement and (iv) Maintenance and Repair. Overhead expenses such as wages and salaries included in the component direction and administration consumes a significant part of the total amount available for operation and maintenance leaving very little for actual maintenance work. The share of wages and salaries have gone up from little under 30 percent in early 60s to near 50 percent in the late eighties (Gulati, **et al** 1994; P.2). Report of various committees[7] and commission reports have suggested from time to time that the operation and maintenance of the existing irrigation project is not given its due share resulting in under utilization of irrigation potential and the reduced efficiency with which the systems are operated. Finance Commissions have also examined this issue and have often allocated operation and maintenance funds for canal irrigation schemes on the basis of the area irrigated by each scheme. The working group on major and medium irrigation for the Eight Plan found that most of the allocated money for operation and maintenance was being spent on staff payments. The central problems, as brought about by various studies including the working group are the inadequacy of funds available to carry out the operation and maintenance activities and to find out ways and means to ensure a higher level of resources for operation and maintenance so that the systems could operate more efficiency.

There-upon, the Eighth Finance Commission (1984) recommended the provision of a consolidated amount of Rs.40.5 per acre of gross irrigated area for purpose of maintenance in all the states and an additional 30% for the hill states like Himachal Pradesh, parts of Uttar Pradesh, sikkim and Jammu and Kashmir.[8] A later committee set up by the Ministry of water resources upgraded this norm to Rs.72.88 per acre per annum of gross irrigated area for operation and maintenance grant taking the base year as 1988. The working group on major and medium irrigation, however, felt that a minimum of Rs.80.1 per acre to 101.23 per acre was required to keep the system in good order. The Tenth Finance Commission (1994) has adopted a norm of Rs.12.50 per acre for the utilized potential and Rs.40.5 per acre for the unutilized potential (GOI, 1994, pp.1-40). The norm adopted for the hill states are higher by 30 percent. A recent study on operation and maintenance expenses found that in the period 1960-61 to 1986-87, the total working expenses (at 1988-89 prices) ranged between Rs.44.13 and 77.70 per acre. Thus, the operation and maintenance expenses are increasing year by year, due to rising prices of other related materials.

Progressive deterioration in the standards of maintenance of sources has been the result of several factors. Before Independence, the government were primarily engaged in the maintenance and operation of the existing irrigation works and took up only a few new works. After Independence, especially since the beginning of planned economic development in the country, systematic exploitation of water resources for purpose of irrigation was

taken up on a large scale through construction of dams/storages(see Appendix-V). A substantial portion of the plan outlay is being spent in almost all the states on new irrigation works major and medium.

OPERATION AND MAINTENANCE EXPENSES IN THE MADRAS PRESIDENCY :

One of the effects of colonial rule in India was the decline of community assets and habits of community working and living. Instead, they instituted individual ownership of productive assets including land, and began to collect all the taxes and charges accordingly. This change had adversely affected many old native institutions that had been ensuring a balanced distribution of the produce among the various sections of the society and protected the delicate ecological balance of the different natural regions. Irrigation tanks in Rayalaseema was one such victim (Atchi Reddy, 1995, P.108). Neglect of the age old practice of **Kudimaramath** i.e., the customary practice of engaging village labour, consequent on the increasing realization of the government responsibility has also been responsible for the present state of affairs while the state was progressively assuming the obligation for maintenance, it was increasingly finding it difficult to discharge this importance it was attaching to new construction, and extension of area under irrigation (P.B.R, 1883; P.1-8). In the choice of investment between maintenance and construction, the state prefers to attach greater importance to construction rather than to maintenance. The remarks of the First Indian Irrigation Commission (1903) were: "It is the opinion of most of the local officers in both the Revenue and Public

works departments that the grants hitherto allowed are insufficient for the purpose" (GOI, 1903; P.112). The same opinion continued to obtain among the officers as also the **ayacutdars** even later also. This is also one of the reasons for inefficiency in quality and quantity of water receiving at the tail end and even command area of the projects concerned. The cumulative effect of these factors over a period of years has been the neglect of the irrigation systems which is assuming serious proportions. The trend has changed after Independence. The planned economy allocated in its budget in sufficient funds for operation and maintenance of major and medium irrigation systems.

The responsibility for the proper upkeep and maintenance of irrigation sources is a obligation and drainage works in the ryotwari tracts of the then Presidency were according to local custom (Kudimaramat) to be attended by the ryots (P.B.R., 1863, pp.4482-84). The main functions of the Kudimaramat were : (i) To fill up gullies or other inequalities caused by rain or the treading of cattle, etc., upon the bunds of tanks and river, channels, (ii) To check the growth on bunds of prickly pear or other similar rank and pernicious weed, (iii) To clear away such underwood from the bunds of tanks as may be considered by the Executive Engineers to be injurious, (iv) To clear out the deposits from tank sluices and from river and spring channels so as to afford a sufficient opening for the supply of water to flow to the fields, (v) To clear and repair the earth work of petty and branch channels, and clear away the accumulations in all channels issuing from tanks which obstruct the flow of water to the

fields, (vi) To keep in order the supply channels of tanks to such extent as is sanctioned by local custom, (vii) To water the bunds of all tanks during rainy weather, (viii) To construct ring dams at breaches, and where necessary to temporarily strengthen the bunds of tanks and channels during the season of cultivation. These functions were met by the ryots for smoothly receiving water from source to the fields.

Irrigation tanks were maintained in a tolerable condition by the **poligars** even though they were oppressive in many respects. The removal of the numerous **poligars** by the British Government resulted in a death blow to some of the tanks whose bends were cutout and the big trees on their bunds were fell down during their protracted struggles with the intruding armies of the East India Company. Private tanks were the main victims as many of them were maintained directly by the **poligars** or by their relatives and subordinates in the villages concerned. The old records of tanks with details of their irrigation and cultivation, their establishment and maintenance were all lost in these disturbances. The institution of **Kudimaramath** which was closely maintained by the **poligars** had lost much of its force with their disappearances. The revenue officers appointed by the East India Company could not command the necessary hierarchical obligation for the effective maintenance of **Kudimaramath**, nor could they find any immediate alternative. The British Government of the 19th century had notified a number of tanks in ruins in the Rayalaseema area including Nellore district and suggested some suitable measures of improvement (Atchi Reddy, 1995, P.116).

Formerly the cultivators had to depend entirely on themselves for the maintenance of these works. If a tank or river canal failed, assistance in restoring it might or might not be attended sooner or later by the state, but no reliance could be placed on such assistance and the people had to rely on their own efforts on **Kudimaramath**. But this system itself was not sufficient to ensure the perpetual maintenance of the tanks/reservoirs. Some repairs were required which were beyond the power of the cultivator to carry out or the works were wrecked by disastrous floods, and in other cases even **Kudimaramath** could not wholly prevent, however, much it might retard deterioration. It thus happened that Government should devote more and more attention and money to the restoration and upkeep of these works, even before the obligation was accepted, on the recommendation of the famine commission of 1880, as a part of its regular policy (GOI, 1903; pp.111-115). The irrigation commission recommended that a systematic devotion of funds to the improvement and maintenance of tanks/river, channels, but they pointed out that, if the cultivators cannot be made to do their small parts. If the ryots are not in a position to do the Government has to meet such works to do.

PRACTICE OF KUDIMARAMAT :

The traditional system of maintenance and repairs to the tanks **Kudimaramath** and **Cheruvumaramath** suffered a severe blow with the enfranchisement of the inams of various denominations in the new settlement introduced in Rayalaseema during the period 1870-1880. About 99% of them were enfranchised at varied rates

of assessment. The Inam Commission found that not less than 8,84,867 acres of land in Kurnool district was occupied as inam in 1860. About 8.75,790 acres were enfranchised in the new settlement at rates of quit-rent, varying from 1/8 to 1/2 of the ordinary assessment. Subsequently, the service of inams of **reddies, curnams**, those of revenue and police persons who revendered state service were compulsorily enfranchised at 5/8 in the rupee of assessment. A number of village servicemen who used to take care of the tanks as functionaries were consequently turned into pilfers of the soil and stones from their bunds often resulting in their breaches during the heavy monsoon downpours (Atchi Reddy, 1995, P.117). But in those areas other than Rayalaseema practice of the system was somewhat different. The collectors such as those of Visakhapatnam, Ramnad and Salem were too vague in the matters of the description of the forms of customary labour performed in their district to permit an exact classification of the labour and in some districts, such as South Arcot and Anantapur (GOI, 1917; p.279). It was reported that some forms of customary labour were sometimes contributed voluntarily while other items were not performed except under pressure. It could be generally seen in the collector's reports that in all cases in which the ryots were threatened with immediate loss of crops or damage they readily and voluntarily contributed such items of customary labour as were necessary to avert the loss. Where, however, the results of neglect were not immediate, neglect was found everywhere and things went from bad to worse till the heavy expenditure had to be incurred. The items of **Kudimaramath** work can be classified into three : digging of chan-

nels in river beds, and repairs and maintenance of tanks irrigating ten acres and less[4].

In spite of such excellent advocacy of the practice by the Commission, the Madras Government found the enforcement of the practice cumbersome and unpopular and consequently chose to implement the recommendation of levy for a cess and enacted the Madras Irrigation (voluntary) Cess Act of 1942 to obviate these difficulties. This Act provides for the levy of voluntary cess for the maintenance of irrigation and drainage works of all kinds which are owned and controlled by the State Government and serving ryotwari tracts and also estate areas not taken over by the Government. There is provision in this Act for the levy of cess in lieu of **Kudimaramat** only when the holders of two-thirds of the land served by the irrigation or drainage works so desire.

OPERATION AND MAINTENANCE EXPENSES IN INDIA AND ANDHRA PRADESH:

While the normal maintenance of sources has been traditionally the customary obligation of the **ryots** the government has been incurring progressively larger sums towards operation and maintenance of Irrigation sources. The Government earmarks every year, in the budget funds for extensions and improvements, flood repairs, pro-rata charges for tools and plant and superior establishment of maintenance and repairs.

Till the year 1965-66, maintenance amounts earmarked in the annual budget of the irrigation department remained at about Rs.1.50 per acre which was considered far too low for the proper maintenance of sources. The joint central team on Agricultural Programmes recommended increase in this rate to Rs.3.50 per acre citing the orders issued by the Panchayat Raj department, fixing the maintenance grants for sources under its control at Rs.3.50 per acre. Further, it was increased to Rs.4.00 per acre (Government of A.P, No.48, 1966). Even this enhancement was considered inadequate for the proper maintenance of sources. In the present inflationary situation the salary of the work charged establishment have been increasing rapidly, with the receipts from farmer and grant from government remaining static and establishment cost increasing due to revision of wages and allowances, cost of labour and materials has also been going up from year to year.

TABLE - 4.9 WORKING EXPENSES AND GROSS RECEIPTS FROM MAJOR AND MEDIUM IRRIGATION SOURCES IN ANDHRA PRADESH (1988-89 CURRENT PRICES)

(RS. IN LAKHS)

YEAR	WORKING EXPENSES	GROSS RECEIPTS	% RECOVERY OF WORKING EXPENSES THROUGH GROSS RECEIPTS
1976-77	985.00	109.20	11.09
1977-78	930.00	99.20	10.67
1978-79	811.00	107.80	13.29
1980-81	1843.92	128.93	6.99
1985-86	3886.52	1435.30	36.93
1986-87	3424.45	341.74	9.98
1987-88	13463.58	1042.30	7.74
1988-89	49098.47	544.07	1.11
1989-90	31553.70	3520.79	11.16

Source : **Report of Comptroller and Auditor General of India**, 1984-85, pp.105-126 and Eighth and Ninth Finance Commission reports, 1984 and 1989, pp.Ann.III-10-19.

The operation and maintenance expenses in respect of major and medium river projects in Andhra Pradesh, is noted that gross receipts has been falling short of total of working expenses. From 1976-77 to 1988-89, the loss increased from approximately Rs.876 lakh to 48555 lakh. in 1980-90 it was Rs.28,032 lakhs (See Table - 4.9). The Table also shows the gross receipts as percentage working expenses find that the gross receipts from major and medium irrigation projects covered only on an average

10 per cent for the whole period 1976-77 to 1989-90. During the year 1985-86 it was 37% which creating a mounting burden of loss to the government.

TABLE : 4.10 **WORKING EXPENSES AND RECEIPTS IN RELATION TO IRRIGATION POTENTIAL UTILIZED BY THE MAJOR AND MEDIUM IRRIGATION PROJECTS IN ANDHRA PRADESH**

(1980-81 CONSTANT PRICES)
(Rs. per acre)

ITEM	YEAR		
	1977-78	1979-80	1984-85
Receipts per acre of Irrigation potential utilized Major and Medium irrigation projects	2	2.1	10.12
Working expenses per acre of Irrigation potential utilized Major and Medium irrigation projects	23	23.2	38.41
Receipts per acre in relation to working expenses (%) per cent	8.78	9.03	26.35

Source : **Central Water Commission,** 1988, Ministry of Power and Water Resources, New Delhi.

Another way of looking into the irrigation receipts in relation to working expenses is to compare the per acre receipts from irrigation potential utilised with per acre working expenses of the same in Andhra Pradesh (see Table-4.10). The data show out the poor recovery of revenue in relation to working expenses.

CONCLUSION:

The analysis reveals that the widening gap between the receipts from irrigation and expenses on operation and maintenance resulted in the paucity of funds for reinvesting. To

sustain the current and future expected level of agricultural development, sufficient and timely water must be made available through the major and medium surface irrigation systems. These systems need to be operated well and maintained efficient to regular repairs. The data indicate that the gross receipts in general fell short of the working expenses, and it is this widening gap which resulted in the paucity of funds for operation and maintenance, and not to speak of any sizable flow into the new investments.

The results reveal a raising pattern of per hectare capital costs over the period of 1950-1990. The average cost of cumulative irrigation potential created through major and medium schemes over this period, increased the per-hectare development cost due mainly to the poor recovery.

APPENDIX-IV-1

TABLE SHOWING COST PER ACRE UNDER ANNUAL IRRIGATION FROM DIVERSION / STORAGE WEIRS IN ANDHRA PRADESH (MAJOR AND MEDIUM)

(RS. IN LAKHS)

NAME OF THE PROJECT	ACTUAL OR ESTIMATED COST (RS. IN LAKHS)	TOTAL AREA IRRIGATED OR UTILIZED OR TO BE IRRIGATED (ACRES)	COST OF PROJECT PER ACRE OF ARE IRRIGATED (RS.)	YEAR OF COMMENCEMENT/ COMPLETION

NOTES :

1. Public investment will have a leading role to play in the form of providing infrastructure as well as in providing necessary research and development support. There is a significant relationship between public investment in agriculture and private investment undertaken by the farmers (Sukhamoy Chakravarty, 1987, pp.75-80).

2. These social overheads are nothing but infrastruces of an economy which facilitate the flow of goods and services between buyers and sellers. Examples of these structural elements are communications and transport (roads, railways, harbours, airports, telephone etc.), housing, sewerage, power systems, irrigation projects etc. These facilities are usually, though not necessarily, provided by public authorities and may be regarded as prerequisite for economic growth in an economy (David W.Pearce (ed.,), 1986, P.204).

3. The trends in real capital costs for new irrigation system in the developing countries show large increases in the costs per hectare of investment over the past three decades. In India, the real cost of new irrigation have more than doubled since the late 1960s and early 1970s (In 1966-69, the real capital cost per hectare was, Rs.2,698 at 1988 prices). The result of these of increases in costs and declining prices is low rates of return for new irrigation construction (Mark W.Rosegrant and Mark Svendsen, 1993, p.21).

4. In order to estimate the inflation rate relevant for capital

outlay on major and medium irrigation schemes in India over time, the Central Water Commission evolved made a method to review designs for all major and medium schemes costs were classified into four broad categories : a) labour and miscellaneous items not included under other heads, b) cement, c) iron and steel, and d) machinery and transport equipment. Their respective weights were judged to be 0.60, 0.20, 0.15 and 0.05, to estimate inflation rates for categories b, c and d. The Economic Adviser's wholesale price index series for cement, iron, steel and ferro alloys and machinery and transport equipment were used to estimate their respective inflation rates for the period 1950-51 to 1988-89. Annual rates of increase turned out to be 6.94% for cement, 8.41% for machinery and transport equipment. The inflation rate for labour and other miscellaneous cost items is rather difficult to estimate due to sizeable beterogaeity, not only of skills within the labour component, but also within other miscellaneous items. Data on agricultural wages have been used to estimate the inflation rate of labour and other miscellaneous cost items. This gives an overall annual inflation rate for this cost category of 7.88% (Central Water Commission, 1989, pp.1-39).

5. A study of Gulati, **et.al.,** (1994) on the development cost of irrigation takes into account the inflation rate as well as the gestation lag phenomenon to examine cost of investment for major and medium schemes. In this study, the concept of pure time preference has been used to account for the time gap between expenditure incurred and benefit obtained. The results indicate that, at constant prices (1988-89 price level) and at different

rates of pure time preference (5%, 7.5% and 10% per annum), the average investment per hectare of irrigation potential lies in a range of Rs.35,084 to Rs.61,814 (Gulati et.al, (1994), pp.1-23.

6. A large number of new projects were taken up in most states, during the plan period (1951-1990), as 236 in First Plan, 139 in Second Plan, 101 in Third Plan, 48 in Annual Plans (1966-69), 127 in Fourth Plan, 404 in Fifth Plan, 68 in Annual Plans (1978-80), 182 in Sixth Plan and 47 in Seventh Plan (Government of India 1989, pp.1-108.

7. Until 1964, irrigation projects were approved on financial criteria, excepting protective irrigation works, such as famine relief works in areas exposed to chronic water scarcity. Later, when new schemes were undertaken, it was felt that the development of irrigation, essential for increasing agricultural production and productivity, was being held up by the rigid application of the financial criterion of rate of return, which was 6% between 1921 and 1949. After Independence, irrigation development was stepped up. The minimum return on investment in the irrigation projects was reduced from 6% to 3.75% in 1949. As a further effort towards improvement, the Nitin Desai Committee (1983), suggested the use of opportunity cost of various inputs and outputs rather than their market prices to reflect their real value. This committee also suggested that in the economic analysis of irrigation projects, the Discounted Cash Flow (DCF) method be followed for the benefit - cost analysis, as it makes clear the advantages of quicker implementation of the project and also

a quicker realization of benefits. The cost-off rate or minimum expected rate of return was 9% for general areas and 7% for drought-prone and flood-prone areas where 75% or more of the dependable flows of the basins had already been utilized (Government of India; 1983, Report of the Committee to review the existing criteria for working out the Benefit-cost ratio for irrigation projects,New Delhi). The National Conference of Irrigation and Water Resources Minister, 1986, remarked on the extremely low water rates that were prevalent in the country and the fact that they were not sufficient to cover even Operation and Maintenance costs (Government of India ; 1986 (Report of the Committee of Ministers for under utilization of Greater irrigation potential, Planning Commission, New Delhi. The Jakhade Committee (1987) remarked on the extremely low water rates that were prevalent in the country and the fact that they were not sufficient to cover even Operation and Maintenance costs. The National Water Policy (1987) emphasis the need that water rates should be such as to cover Operation and Maintenance charges and a part of the fixed capital cost (Government of India, 1987, National Water Policy, New Delhi). This was reiterated by the various Finance Commissions and Public Accounts Committee, with Government bodies like the Public Accounts Committee (Government of India, Public Accounts Committee, 1983, New Delhi) noting that public investment in irrigation was resulting in investment in irrigation was resulting in enormous losses to the National exchequer. It opined that irrigation scheme should yield enough to pay for maintenance and operation and depreciation charges along with some interest on the capital invested. It recommended a five -

yearly evaluation of projects to find the extent to which expected benefits have been achieved and to decide what has to be done in future in order to extract maximum benefits. The Fifth Finance Commission recommended that Operation and Maintenance cost plus 2.5% of the capital to be recovered. This rate of 2.5% was subsequently brought down to 1% proposed by Sixth and Seventh Finance Commissions. The Eighth Finance Commission brought this rate down to zero, a position which was reiterated by the Ninth Finance Commission.

CHAPTER - V

EVOLUTION OF THE WATER RATES IN INDIA : 1850 - 1990

INTRODUCTION:

The irrigation policy of the British rulers was marked by an apparent change in the fixation of water rates. This was mainly because of strong commercial motivations of the government. The need for rationalistion of water rates arose with the commencement of the irrigation under major river deltas in the early 1850's in the Madras Presidency. The basis of charging for water in the British period, when supplied by Government works, was chiefly the area irrigated. But different systems of charging were in operation in different parts of the Presidency at different points of time. An attempt is made here to trace the origin, evolution and rationalisation of the water rates in the British period as well as in the Independent India in general and Andhra Pradesh in particular.

WATER RATE POLICY :

There are fundamentally two main considerations in fixing water rates, namely the consideration of the cost involved in the construction of an irrigation project, and the benefits accruing from irrigation to the users of water. Various principles have been laid down for determining the viability of individual irrigation projects. G.N.Taylor, in 1858 found that increased reve-

nue collections of Government in specific areas were due to the construction of anicuts in the Godavari and Krishna districts (GOI, 1858, pp.19-20). A concrete measurement was undertaken in Taylor's Report chiefly in terms of the collection of revenue by the Government.[1]. The measurement was mostly confined to the collection of land revenue. It was only in few cases that it was extended to sources of revenue other than land revenue and water charges. As a matter of fact there seems to have been an undue emphasis on the revenue receipts from irrigation projects and most estimates and calculations in connection with the assessment of economics of irrigation development concerned themselves with the direct return of investment (Gadgil, d.R., 1948, p.2). Thus, during the 19th century the test for economic soundness of an irrigation project in India was based chiefly on the direct returns on the investment.

Irrigation projects were regarded as "productive or unproductive" according as they yielded a net revenue above or below a certain fixed percentage (4%) calculated at the "sum-at-charge", ten years after the completion. The sum-at-charge constituted the total capital outlay and the arrears of interest. The determination of the rate of return was made by the Government of India from time to time. This criterion was also adopted by Select Committee of the House of Commons in 1879 which stated that, "the financial results of irrigation are, in the opinion of the committee, the best test of their utility[2] (Public Works Department, 1879, pp.III-XXI). This principle was followed since then and the rate of return required, before an irrigation pro-

ject could be considered as financially productive and economically sound was fixed from time to time according to the prevailing conditions.

There was great dissatisfaction with this rate of return towards the close of the past century in India due to the realisation of the fact that there were many indirect benefits from irrigation to the community at large. And the financial test of economic soundness of an irrigation project was too rigorous to present a correct picture of the economics of irrigation.

The Government of India, therefore, appointed the Royal Commission on Irrigation in 1901 to re-examine this issue. But the report of this Commission also favoured the productivity test which was adopted by Select Committee (1879). The Report stated that it had been often urged that the indirect advantages of irrigation in India were so great and incontestable that the question of the direct financial returns which might be anticipated on the capital outlay was one of minor importance to which the very little regard should be paid. But in the context of water rate on the productive works, it should include a charge in the supply of water which would cover primarily the debt charges and overhead expenses (GOI, 1903, p.27). This was again observed by Taxation Enquiry Committee (1924-25), that it is difficult to evaluate exactly the extra net income of land from irrigation and that this being so the simple thing to do would be to charge a fraction of gross produce of irrigated land as water rates (GOI, 1926, pp.99-110). But the Committee held that the direct returns from irrigation project were maintained.

WATER RATES IN THE MADRAS PRESIDENCY, 1850-1953 :

The need of legislating in order to clearly define the position of the state in respect of irrigation was recognized as early as 1856 when the Governor-in-Council directed the drafting of an Act to set out "what is clearly the common law of the country, viz., that rivers and natural streams as well as springs in unoccupied or Government land belong to Government"[3] (Dharma Kumar, 1975, pp.230-231). The rule noted in section I of the Act of 1865, that "whenever water is supplied or used for purpose of irrigation from any river, stream, channel, tank, or work belonging to or constructed by Government it shall be lawful for the Government to levy at pleasure on the land so irrigated a separate cess for the use of the water, which cess shall be additional to any land assessment that may be leviable on the said land as un-irrigated or Punjah" (Government of Madras, 1865, pp.130-131). All lands now permanently supplied with the means of irrigation for a single wet crop and which are cultivated as nunjah and have actually been irrigated for two or more seasons prior to the 18th July, 1863 were classed as irrigated and charged Rs. 3 per acre per annum for water, in addition to their fixed land assessment. Whenever water was supplied for a second crop of any description on nunjah land, in addition a water rate of Rs.3 per acre was charged for the same.

Except in the Godavari and Krishna deltas and on the Kurnool-Cuddapah canal, the assessment on irrigated land was consolidated, and the shares due respectively to "land" and "water"

could be only approximately determined. In the Godavari and Krishna deltas and on the Kurnool-Cuddapah canal, the assessment on irrigated lands was not consolidated, but a separate water rate was levied on the area irrigated owing to the works were constructed by the Government. For the determination of the share due to irrigation resulting from the disintegration of consolidated assessments, elaborate rules were framed (GOI, 1879, P.38). In the case of single wet crop the rules were: where assessments had been revised by the Settlement Department, the consolidated assessments were resolved into land and irrigation revenue respectively, by assigning to "land" the amount proper to dry lands of the same class and sort in each village and the remainder to "water" (GOI, 1879, P.39), where settlements had not been revised the average dry rate of the village, or where that was not available of the **talooks**, or where that could not be determined of the district, the rate was applied to the total area irrigated. The product was then assigned to "land" and the remainder to "water". With regard to double crop lands, the charge for the two crops was consolidated-the charge for the second crop being essentially in the nature of a water-rate.

TABLE 5.1 WATER RATES IN THE GODAVARI AND KRISHNA DELTAS AND ON THE KURNOOL-CUDDAPAH CANAL - 1869

(IN RUPEES)

NATURE OF CROP	GODAVARI AND KRISHNA DELTAS	KURNOOL-CUDDAPH CANAL
Single wet crop, per acre	4	4
Second wet crop, per acre	4	3
If compounded for both crops for not less than five years.	6 1/2	6
Single dry crop	2	1
Second dry crop on irrigated lands if not compounded	2	1
Garden crop	8	6
Garden crop if compounded for not less than five years	6 1/2	-
Crops requiring frequent floodings	-	3

Source : Based on **C.D.Maclean,** 1987, P.411

The rates fixed according to the Revenue settlements, and the difference in the water-rate both in Godavari, Krishna and Kurnool-Cuddapah deltas were due to the variations in duration and supply of water to the tracts, (see Table 5.1). Where both wet and dry crops were sown.

In tracts like the Krishna and Godavari deltas, the assessments of irrigated lands were made up of the assessment of the lands considered as dry with the addition of a separate water rate. In all districts of Madras Presidency that had been resettled by the Settlement Department, the assessments of the same class and sort of dry lands could be at once determined. In other cases, they were approximated based chiefly on the application of average dry rates to wet areas, the product representing the land assessment proper and the balance of the wet assessment

the share of it that was due to irrigation. The incidence of irrigation revenue per acre for each class of works, ordeduced from the same accounts on the works of Classes I and II are worked out (see Table 5.2).

TABLE-5.2 INCIDENCE OF IRRIGATION REVENUE UNDER EACH CLASS OF WORK - 1869

CLASS OF WORK		AVERAGE IRRIGATION REVENUE PER ACRE (RS.)
Works which capital and Revenue Accounts are kept :		
I	Productive public works	3.27
II	Public works not classed as productive	3.28
	Works for which neither capital nor revenue accounts are kept :	
III	Works for which in a continuous records of expenditure is maintained individually	4.93

Source : Based on C.D.Maclean, 1987, P.419

The greater part of the amount of water-tax was levied in the delta **talooks** irrigated from the Godavari and Krishna **anicuts**, where all lands were assessed at the dry rates, water tax being separately imposed on the customary **nunjah** lands, which elsewhere paid a consolidated assessment. This was the practice till 1869, and the Board of Revenue then condemned the system on the grounds that, the ryot was in the hands of the **Karanam** who was already too powerful, frauds were perpetrated on Government, the cultivator never knew exactly what was really due by him, the rates themselves were numerous and unfair (P.B.R, 1869, Para-7). This led to the introduction in 1874 of a system of fixed water-rates Rs.4 per acre being charged for a wet crop grown on dry land and Rs.2 for dry crop. A distinction between occasional and systematic irrigation was drawn in 1890 and crops systemati-

cally irrigated became chargeable as wet (P.B.R. No.272, 1890). Prior to 1890, the charge for water was regulated by the class of crop raised, but not by the number of waterings it received. In that year a charge was made by the term "dry crops" was hardly appropriate to crops which were regularly irrigated and it was therefore directed that when crops, which might be grown as dry crops, were systematically irrigated, they should be charged as wet. Six years later it was pointed out by Nicholson that the systematically irrigated crops were not wet in the same sense as paddy. Thereupon the Board of Revenue of Madras recommended a rate intermediate between the wet and dry rates was imposed on dry crops systematically irrigated and charged on crops grown in beds and irrigated at regular intervals (Government of Madras, No.3038, 1896).

The Board in reporting on the effects of this scale in 1903, said that the intermediate scale was complex and uncertain in its application, that the distinction between systematic and occasional irrigation was impossible to maintain with fairness and that it gave great scope for fraud and black mail (Government of Madras, 1903, pp.271-281). The Government then proposed to abolish the intermediate systematic-irrigation rate and to base all water-rate on a definite classification of crops as `dry' or `wet' in each district.

The Board in reply condemned the fixed water-rate system. Its objections to this system were that it made a distinction

between systematic and occasional irrigation, that it assumed only two classes of irrigation sources where as in most districts there were four or five or six classes, that it involved a classification of crops, a procedure inconsistent with the principles underlying the **ryotwari** settlement, and that it penalized the bad lands and let off the good lands too lightly.

The Board recommended in its place the differential system, which states that, when a dry land is irrigated, the appropriate water rate is the difference between the wet assessment and corresponding dry assessment for the same class and sort of land. It imposed the same charge for raising a wet crop like paddy on dry land as for raising there on an irrigated dry crop of poor quality like ragi. On the other hand, it had the advantage of being more equitable than the existing arrangement, in as much as under it the poorer soils should pay less than the richer and the charge for water should be proportionate to the known fertility of the soil.

Another advantage incidental to the application of differential water-rates was that as "irrigation sources are divided into four or five classes for purposes of fixing the wet assessment against only two for water-rate, the scheme will make greater allowances for differences in the capacity of the irrigation sources than is possible under a uniform water-rate" (Government of Madras, Leach's Report 1923, pp.34-35). The Government agreed and said that "the adoption of a graduated scale of water-rates

based on the settlement classification of the soil and on a simple division of crops into two main groups 'wet' and 'dry'. The Government accordingly drew up a scheme in 1906 for water-rates in varying terms of the difference between the wet and dry assessments. The scheme was introduced first in Kurnool district.

Again in 1913 the Board condemned the differential system on the grounds that it was inefficient and pointed out that the fixed rate system caused no serious injustice though open to the objection that, it did not take sufficiently in to account the adequacy of supply. If the relative productivity of soils be taken into consideration in determining water-rate the best method would be to group the dry lands of each district into two or more large, classed with reference to their supposed value under irrigation assigning a fixed rate to each class. It was really unnecessary to attempt to discriminate relative productivity,but it was desirable that the quantity of water available should not be ignored in fixing the charge for water, and that such quantity could be allowed for by attaching a separate fixed rate to each group of source in a district (Government of Madras, Leach's Report, 1923, P.35). On these grounds the Board urged, the abolition of the differential system and the introduction of a system of fixed water-rates varying with the adequacy of supply in the irrigation source, the abolition of the destruction between systematic and occasional irrigation, and the grouping of irrigation sources for purposes of water rate into two groups.

The Government decided to discontinue the differential system and propounded a scale in which irrigation sources and soils were each grouped into three classes. Some revised rules for the levy of water-cess on dry lands irrigated from a Government source or work in lieu of the existing rules in relating to standard scale of water rates, the Godavari, Krishna and Guntur districts, the Kurnool-Cuddapah canal, Kurnool district etc. Irrigation sources were divided into three groups for purposes of charging water rate (Government of Madras, 1923, P.66). Irrigation sources which could ordinarily afford a supply of water for not less than eight months in the year were placed in the first group; irrigation sources which could afford a supply of water from five to eight months were placed in the second group. Other irrigation sources were in the third group (see Table - 5.3). Second and third wet crop would be half the rate charged for a single wet crop with variation to supply of water.

Source : Government of Madras, Revenue, No.1089, dt.19.07.1923 (Ms), P.66.

From 1874 to 1906 the process of development was from the simple to complex. In setting a charge for water supplied for irrigation, the factors which may be considered were the area of the land irrigated, the quantity of water supplied and the period during which it was supplied, the soil of the land irrigated and the effect on the productivity of the soil caused by bringing water to it, all these factors and more were considered in the settlement of a consolidated wet assessment.

There were several systems for levying separate water rates in the Madras Presidency. They are : wet assessment, differential water rate, volumetric rate, and fixed water rate.

CONSOLIDATED WET ASSESSMENT :

Consolidated wet assessment was the system of levy of charges for irrigation adopted in erstwhile Madras Presidency, the princely states of Mysore and Hyderabad and parts of Bombay Presidency. The charge for water under this system was merged in land revenue proper and fixed on settlement principles, with due regard to soil characteristics and the productive capacity of lands. Madras was the only state in India which had adopted net produce as the basis of land revenue assessment (Government of Madras, 1878, P.1143). During the settlement, net produce was derived by deducting the cultivation expenses from the gross value of produce. The Indian Irrigation Commission 1901-03 was of the opinion that "consolidated wet assessment system is evidently the most simple and where the area irrigated is subject only to slight changes as in the rice fields of the deltas in

Southern India" (Government of India; 1903, pp. 69-98).One of the essential preliminaries under this system was an accurate survey and soil classification of each individual holding.

The estimates of net produce in the Madras system, were the result of conjecture as of investigations tempered by informed judgment, since the estimates in regard to commutation rates and cultivation expenses had a definite bias towards under estimation of the value of net produce, the final rates adopted were in actual practice less than the theoretical standard of 50% of the net produce (Government of Andhra Pradesh, (1959), pp.498-500). Under the Telegana system, the role of scientific soil rating in the fixation of land revenue rates was considerably minimised due to the high degree of description enjoyed by the settlement officers. While in the Andhra area, the unit of settlement was tract comprising one or more taluks, the unit for the settlement in Telengana was a group denoted by a maximum rate of assessment which comprised various groups villages in various taluks (Government of Andhra Pradesh, 1959 : pp.498-500). The advantage of the ryotwari settlement principle was that an attempt was made to relate the land revenue to the productivity of the soil as it was the productive capacity of the soil which determined the output which enabled the ryot to pay a portion of this output as land revenue. The original settlement was based on a soil classification done in detail and with great care. The relative values of the lands were reflected in the soil classes they carried and the relative rates of dry land revenue or wet assessment was depend-

ent on this soil rating. Consolidated wet assessment method of levy of charges for the use of water, when they stated that it avoided multiplicity of tax and reduced, to some extent, the cost of assessment. The system also provided for compulsory payment of the water charge which ensured a minimum return on the project. The rate of tax was dependent on the value of water to the cultivator which was influenced by the nature of the soil of the land under irrigation. The Maharastra Irrigation Commission was of the view that this system was well suited when a single category of crop alone was grown as it used to be during the days of settlement in the Madras Presidency (Government of Maharashtra, 1962, pp.67-75), as the several irrigators got the same average benefit from an acre from year to year due to uniform cropping pattern.

SOME DEFECTS OF CONSOLIDATED WET ASSESSMENT IN MADRAS PRESIDENCY:

During the settlement, calculations in the Andhra Area were the ascertainment of the standard staple grain. For irrigated land the standard grain adopted was uniformly paddy to the exclusion of other irrigated crops presumably due to the non-existence of the practice of irrigating dry crops then which is very much prevalent and popular today. This practice has led to the inequality of burden of tax between the lands cultivated with commercial crops and food crops.

The determination of the standard grain which in all cases of wet cultivation had been paddy, the next defect in the settle-

ment process was the ascertainment of the outturn of such crop on lands of different soils. In the early stages of settlement work, this was done after numerous crop cutting experiments on different classes of soils. But after 1882 the actual crop cutting experiments were dispensed with in general and the average of the out turns of the adjoining districts was adopted. Actual experiments of outturns were conducted only in special cases (Government of Andhra Pradesh, 1959 : pp.498-500). The results of these experiments could not be considered as the correct standard for the reason also that they were likely to have been affected by the seasonal conditions of the years in which the experiments were conducted. The grain outturns required to be committed into money value since the assessment was payable in cash. There was no uniform method adopted for computing the commutation rate in the settlements conducted in the earlier years. But after 1885, the prices of 20 non-famine years in the preceding year of settlement were taken into account in working out the commutation rates.

In the Telengana area, water class value was also taken into account besides soil value while fixing water rates depending on the character and the value of the means of irrigation assigned to each unit of land. For the purpose of Pani classification or water classification, a distinction was made between sources having an ayacut of 30 acres and above and those having ayacut below 30 acres (Government of Andhra Pradesh; 1973, pp. 193-220). In the Telengana system, there had never been any attempt to fix the average cost of cultivation even on a rough way as was

done in the Madras system or to find out the net produce and then to fix the assessment equal to the money value of a certain percentage of the net produce calculated with fair commutation prices (Government of Andhra Pradesh, 1973 : pp.193-220). The empirical method excluded, by definition in precise concept as to the tax base and the share of the state eliminated by implication, any systematic and scientific procedure in fixing the rates. The consolidated wet assessment method of levy of water charge, related to the productivity of the soil, could be said to have existed then when settlement was done but could not be considered to be reflective of the present productivity. On the other hand, the pattern of agricultural production vastly changed in recent years with the more efficient functioning of irrigation works and the improvement in prices and yield of different crops especially in commercial crops, which were the reasons to narrow down the existing settlement calculations which changes occured in prices of different crops.

REPLACEMENT OF CONSOLIDATED WET ASSESSMENT :

Owing to some defects of the wet assessment, the Government considered the system as inefficient and recommended abolition of consolidated wet assessment. Then all registered wet lands would have to be hereafter treated as dry liable to pay land revenue like any other dry land. These lands would be charged, in addition, an appropriate water rate for the supply of water. The process of abolition was as in 1868. The Secretary of State laid down as the policy that, in order to justify the expenditure of borrowed money on the construction of irrigation works, the

increased returns from the works should yield on income at least equal to the interest on the outlay on the works, that a clear account of the returns directly due to the irrigation should be maintained.

The controversy regarding the differential and fixed water rates began in 1878 in various regions of Madras Presidency. Mr. Wilson, the Special Officer for the compilation of Revenue Receipts, pointed out that "in the case of districts to which the separation of the settlement department have been extended, the resolution is easy; the class of sort of the wet land being known, and in districts which have not been resettles, the facilities for thus determining at once the revenue due to irrigation are thus wanting but an approximation to its value may be obtained by a comparison of the average wet and dry rates of the occupied lands in the village" (Government of Madras, 1878; P.1445). But the Board of Revenue did not agree. According to them, it was necessary either to assume a fixed water rate, or to take as water rate the difference between the dry and wet assessment of every field. As regards the first alternative, the Board held that it was impossible to assume a fixed water rate as the charge for water always varied with the soil and position of the land, while in regard to the second, it pointed out that although it was not unreasonable to assume the difference between the wet and dry rates as the charge for water, the field by field separation of the irrigation revenue in settled tracts would be entire burdensome work.

They accordingly issued the following rules for general adoption in this Presidency. On the lands in the Krishna and Godavari anicuts where the land tax and water rate were distinct, the amount credited to irrigation works was to be the total demand for water rate minus the actual remissions of land tax and water rate granted on account of excess or deficiency of irrigation. In the case of consolidated quit rents on usual wet inams, one-third of such quit rents was to be taken to represent the land tax and two thirds were to be taken as the irrigation credit. No part of the peshkush on zamindari lands irrigated from Government works would be included in the irrigation credit. On all lands except those above provided for where the land tax and water rates were consolidated the average dry crop rate of the village if this could be conveniently ascertained or of the district in other cases is to be applied to the irrigated area. The product of the dry rate multiplied into the irrigated area would then be deducted from the total wet revenue collections. The following water rates are to be included in irrigation credits : the whole charge for second crop, the water rate levied on dry lands converted into wet, the water rate on dry crops watered and the water rate on zamindari dry lands inams other, than usual wet inams paying consolidated rents.

The Board in 1917 proposed to adopt a fixed Percentage of total assessment under each source as the share due to water. The percentage was fixed in 1917 on the actual assessment of the previous ten years. A further revision was made regarding per-

centage in 1930 subsequent to resettlement.

The observations of the Ragavendra Rao, Subrahmanian Committee and S.R. Kaiwar Committee regarding this issue, indicate very clearly the undesirability of splitting up of consolidated wet assessment and treating the portion attributable to water in consolidated wet assessment as the water rate to be charged on these lands. Ragavendra Rao pointed out that the fixed rates to be decided in replacement would be arbitrary and that if they were fixed so low as to be even lower than the standard rates, they would press lightly on good soils and if they were fixed high, they would effect poorer soils adversely (Government of Andhra Pradesh, 1973; pp. 200-20). Now the fixed water rate in force in the Krishna-Godavari deltas, the standard scales of water-cess and the uniform water rates now enforce were liable to this charge. But, the fixed water rate ignored the relative fertility of the soil (Government of Andhra Pradesh; 1973, pp. 200-20). Another objection was that abolition of consolidated wet assessment will be a difficult, laborious and cumbersome process and that it would necessitate extensive azmaish of all wet lands (Government of Madras; 1951, pp. 62-67). Mr. Kaiwar objected in regard to levy of fixed assessment and raised that soil, rain fall and drainage facilities being different from district to district one uniform set of rates could not be fixed for all districts alike (Government of Andhra Pradesh, 1973, pp. 200-20). However, in parts of Andhra Pradesh the consolidated wet assessment system existed due to unrelated soil fertility. Governments like Orissa and Mysore abolished the consolidated wet

assessment and replaced it by appropriate dry rates and water rates.

DIFFERENTIAL WATER RATES :

The differential water rate proceeds on the principle that, when a dry land is irrigated, the appropriate water rate is the difference between the wet assessment and the corresponding dry assessment for the same class and sort of land (Government of Madras; 1931, P. 1-37). The system was in force in the districts of Srikakulam, Kurnool, Cuddapah, Anantapur, Chittoor and Nellore, except in the tracts covered by the standard scales of water cess or projects for which special rates have been specified. The rates of water cess chargeable under the differential water rate system in terms of dry and wet assessment (see Table 5.4).

TABLE-5.4 **DIFFERENTIAL WATER RATES**

NATURE OF CROP	RATES
For a single wet crop	The difference between wet and the dry rates at which the land is assessed.
For a second or third wet crop	One half of the charge shown against item 1 plus half of the dry assessment.
For a first, second or third dry crop	One third of the charge shown against item 1
For Sugarcane, betel plantation and other wet crops which ordinarily remain on the ground for more than six months.	The sum of the charge specified against item 1 and 2
For dry crops which ordinarily remain on the ground for more than six months.	One and a half times the charge shown against item 3

Source : **Standing orders of the Board of Revenue (Land Revenue Settlement area Miscellaneous) 1931.**

This system was a corollary of the consolidated wet assessment system. In Telengana area, whenever a dry land was irrigated, the corresponding wet assessment was charged in lieu of the dry assessment. In other words, a system of differential water rate was in force in the Telengana area also.

In the then Madras Province, the suitability of the differential water rate system vis-a-vis the fixed wet rate system was the subject of a long controversy between the years 1905 and 1923. The Government of Madras, in 1918, accepted the view that the most satisfactory system of levy of water cess was the one in which sources were grouped according to the quality and quantity of supply afforded by them, and the crops were classified in a reasonable manner. The Government decided that the system of fixed water rates was the suitable for the Madras state. The relative merits of the fixed and differential water systems were examined very thoroughly (Paragraph 19-31 of the proceedings of the Board of Revenue No. Mis. 3009, dated 22nd October 1939 pp. 169 to 175) when the Board considered clause-8 of the Land Revenue Assessment Bill then under consideration. Majority of members in Board of Revenue opposed the proposal to adopt differential water system as normal system in the province through this clause. Clause 8 of the Land Revenue Bill, sought to make the differential water cess system the normal system in the then Madras Province in preference to the fixed water cess which was to be the exception.

The Board was of the view that the differential water rate system has a misleading appearance of scientific accuracy, but it was not really even theoretically sound. All the officers who had experience of the differential water rate system, condemned it and the theoretical perfection claimed for it was disproved. The fixed water rate system extending to the sought to avoid on un necessarily large number of rates and such limitations of the number of rates was obviously desirable from an administrative point of view. Under the differential water rate system this consideration was ignored and the number of rates depended upon the number of dry tarams and corresponding wet tarams of the irrigated land which were liable to pay water cess.

Dry assessment had been fixed with reference to the productivity of the land in terms of purely rainfed dry crops of the varieties common in the tract. They argued that "dry tarams do not therefore give any correct indication of the relative values of the lands under those tarams if they are irrigated". A soil which was good for dry crops might not be equally good for wet crops and in so far as the differential water rate formula assumed a close correspondence between the gradations of wet and dry, it rested on an unsound basis (P.B.R, 1939 : P.169-175). In the Cuddapah and Kurnool Districts, an attempt was made to get over this difficulty by assigning a double classification to each irrigable dry land.

In the case of large irrigation systems, the question of a "Fit return" was an important consideration and the differential water rate system was unsuitable. In the case of tanks and other upland sources which were not connected with anicut system, the amount of water available over and above the requirements of the registered wet ayacut would be limited (P.B.R, 1939 : pp.169-175). It was not therefore unreasonable that the ryot growing a wet crop on dry land should be asked to pay more than on wet and dry. The registered holder of wet land had to pay the wet assessment whether he took the water or not, while the owner of a dry land had normally the option to take water or not as he liked and he had to pay water cess only if he took water and on the area which was actually irrigated.

The arguments in favour of the differential water rate system was that it was elastic, while a system of fixed water rates would press heavily on the poorer lands and lands in the tail-end of irrigation sources in the deltas. In the Krishna and Godavari deltas two groups were considered sufficient. Irrigation sources in the uplands in the Godavari and Krishna had been grouped in three groups for purposes of water cess. The advantage claimed for this system was that it enabled the charge of a water-rate on a land which would be commensurate which the yielding capacity of the land and was thus free from the objection usually levelled against a fixed water rate, namely that the same flat rate was charged both for a poor land and a fertile land. It is a well-known fact that soils of different classes did not

react to irrigation in the same proportion. Clay soils which were the best suited for dry crops were not so good as loam for wet crops. The best dry land of regarclay under irrigation could not be compared with the best wet land. "It was for these reasons that the Indian Taxation Enquiry Committee 1924-25 pronounced this system as unsound in theory and exceedingly clumsy in practice" (Government of Madras; 1926; pp.110-120). The Land Revenue Reforms Committee of Madras under the chairmanship of M.V. Subrahmanian, had also examined "the relative merits of fixed water rate system and differential water rate system and recommended that the system of fixed water rate is preferable to the differential water rate system, and that it should be introduced in the districts where the differential water-rate system is now in force". The committee highlights the Raghavendra Rao recommendations that "the advantage from differential water-rate system is only of a limited character, as the corresponding wet rate adopted need not necessarily be in the appropriate wet rate for the land in question (Government of Madras; 1951, P. 62-67). So the Subrahmanian Committee further recommended for the levy of water cess the adoption of the fixed water-rate system in preference to the differential water-rate system and the correlation of the standard scale of water-cess to the current level of prices, and the project scale of water-cess to the standard assessment.

The foregoing considerations reveal that the differential water rate systems had nothing to commend. The differential water-rate system being a corollary of the consolidated wet assessment method could not continue once consolidated wet as-

sessment was abolished. The reason was that the differential water rate system did not have a set of standard rates and hence it was discontinued.

VOLUMETRIC SYSTEM :

Fixed water-rate could be a unit rate, or crop rate, seasonal rate or project rate. When a rate is prescribed for a unit of water, it is called volumetric rate. A volumetric supply system could be conceived of in two ways : supply of water measured with the help of a meter and charging water rate on the basis of the acreage irrigated irrespective of water consumed, and measuring the water supplied for irrigation, with the help of a meter and charging water rate on the quantum of water consumed for irrigation. This second method involved the ryots observed economy in the use of water and thus avoiding wastage of water.

It was an attractive idea to many irrigation officers that the true method was to sell the water by measure at the bank of the distributory channel on the assumption that under this system the self interest of the cultivator would induce hire to make every effort in economising water. The Indian Irrigation Commission 1901-03 had examined (Government of India, 1903, pp. 90-98). The question of volumetric charging in great detail and the major hindrances noted by the commission towards adoption of the system, were in the initial stages, the cultivator would be diffident to adopt the system, as they would not know in advance the likely charges to be paid, the cost of measuring water for individual fields would be prohibitive, cost of irrigation will

vary with the distance from out let to field on account of transmission losses, irrigation requirements would be highly varied and a year of good rainfall would demand less water and thus lesser return where as in a dry year the charges would be more when the cultivator might be getting only very low return from the land, payment would become obligation once water was let out through canal system, and difficulty was anticipated in fixing suitable rates. Consequently, the Commission did not favour the idea of volumetric charging.

The Taxation Enquiry Commission, 1953-54 agreed with the Indian Irrigation Commission's (1901-03) recommendation that "the emphasis should be on a system of distribution by volume rather than on assessment as the mechanical aspect of measurement of water present very great difficulty and as the practice is liable to serious abuse on the part of petty officials" (Government of India 1953-54, pp. 155-203). Another study also came to the conclusion that the system of charging for water according to volume supplied, though, theoretically, more scientific than any other, was not recommended as it would involve a large initial investment for meters and supervisory staff (N.C.A.E.R; 1959, pp.68-74). After considering the advantage of volumetric charging as Nasim Ansari recommended, "the right thing clearly would be to fix rates for different crops in proportion to the quantities of water used by them, and the most precise method of doing this would be volumetric charging" (Ansari, 1968; pp. 71-73). The difficulty involved in its introduction was the high cost of installation of meters etc. The proper maintenance of adminis-

trative machinery regarding this system was not advisable in the present circumstances.

FIXED WATER-RATE SYSTEM :

Fixed water-rate system is one in which the charge for use of water for irrigation is levied at a fixed rate related to the nature of the crop or the season of cultivation on the basis of the extent irrigated or the quantum of water supplied without reference to the fertility of the soil (Government of Andhra Pradesh, 1973; pp. 100-114). Fixed water-rates in force in the state could be grouped into three categories viz., the standard scale of water cess, the special project water rates, and the new project rates.

STANDARD SCALE OF WATER CESS : This rate was in force in parts of Andhra other than the areas in which the differential water rate was applicable in the case of sources for which no special project rates had been fixed.

TABLE 5.5 STANDARD SCALE OF WATER CESS ON DRY LANDS IN MADRAS PRESIDENCY :1931 TO 1956

(IN RUPEES)

DESCRIPTION OF CROP		CHARGE PER ACRE					
		FIRST CLASS SOURCE			SECOND CLASS SOURCE		
FIRST CROP	SECOND CROP	I CROP	II CROP	TOTAL	I CROP	II CROP	TOTA
Wet	Wet	8.00	4.00	12.00	6.00	3.00	9.00
-DO-	dry, systematica-lly irrigated	8.00	3.00	11.00	6.00	2.25	8.25
Wet	dry Occasionally irrigated	8.00	2.00	10.00	6.00	1.50	7.50
Dry, systematically irrigated	Wet	6.00	5.00	11.00	4.50	3.75	8.25
-DO-	Dry, systematically irrigated	6.00	4.00	10.00	4.50	3.00	7.50
-DO-	Dry,Occasionally irrigated	6.00	3.00	9.00	4.50	2.25	6.75
Dry Occasionally irrigated	Wet	4.00	6.00	10.00	3.00	4.50	7.50
-DO-	Dry,systematically irrigated	4.00	5.00	9.00	3.00	3.75	6.75
-DO-	Dry,occasionally irrigated	4.00	4.00	8.00	3.00	3.00	6.00
Sugarcane			12.00			9.00	
Anyother crop (requires water for more than six months)			12.00			9.00	
Third crop if	Wet		4.00			3.00	
	Dry		2.00			1.50	

Source : Appendix I of Standing order No.4, Paragraph, 2, P.164-165, B.S.O.I.

Irrigation sources were divided into two classes for purposes of charging fixed rate of water cess (see Table - 5.5). Irrigation sources placed in the first or second group by Settlement Department should be treated as the first class, and those placed by the settlement Department in group lower than the second should be treated as second class. In the district of Anantapur, however, irrigation sources classed in the third group by the settlement department should also be treated as first class. It must be mentioned here that the standard scale was originally fixed as far back as 1873 and remained unchanged till the year 1956.

2) **SPECIAL PROJECT WATER-RATES** : Finding the standard scales in force to be too low as compared to the quantum of investment, special rates came to be fixed for irrigation under different projects at different times as and such irrigation projects were completed taking into consideration the quantum of investment on the project, the assuredness of supply from the source and the ability of the ryots to pay a certain fee. Whereas the standard scales and the differential water rates were applicable to areas, the special project rates were applicable to particular projects the rate varying with the project (see Table - 5.6). Such special project rates were the scale of water in the Krishna and Godavari delta systems.

TABLE-5.6 SPECIAL PROJECT WATER RATES IN KRISHNA, AND GODAVARI DELTA SYSTEMS : 1931 TO 1956

DESCRIPTION OF CROP	RATE PER ACRE	
	I CLASS IRRIGATION	II CLASS IRRIGATION
	RS.-ANNAS	RS.-ANNAS
First crop, if Wet	12.50	10.00
First crop, if Dry	6.25	5.00
Second Crop, if Wet and following a first Wet crop	6.25	5.00
Second crop, if Wet and following a first Dry crop	12.50	10.00
Second crop, if Dry	6.25	5.00
Third crop, if Wet	5.00	4.00
Third crop, if dry	2.50	2.00

Source : **Standing Order** No.4, Para.2, PP.164-65 of B.S.O.I.

3) **UNIFORM RATES** : New project rates or uniform rates could not be classified a separate category. These rates were also applicable to particular works or projects (see Table 5.7). These rates happened to be the highest of all the project rates.

TABLE-5.7 UNIFORM RATES OF WATER CESS : 1931 TO 1956

DESCRIPTION OF CROP	RATES PER ACRE RS.- ANNAS
For the first irrigated Wet crop	15.00
For the first irrigated Dry crop	10.00
For a dufasal crop	22.50
For the second or third irrigated crop	7.50

Thus, in the British administration there were several systems of charging irrigation water in different parts of the country. Hence, the British Government invented a separate and uniform system of charging the irrigation water to suit the newly emerging irrigation environment. The uniform and fixed system prevailed in the initial stage of the British rule. Later the differential water rate system was introduced in 1909 and tried for some years. Since it proved to be very complicated in practice, again the fixed and uniform water rate system, with some modifications, was introduced.

WATER-RATES IN THE INDIAN STATES :

Water rates in India vary not only among states but also among canals of the same state. These variations and inconsistencies in water rates in India were attributable to the peculiarities of the particular historical forces which went into

their formulation of water rates, which, in most cases were the inheritance from either the colonial past or from the erstwhile princely administration. They emerged as adhoc arrangements to be substituted by consistent policies later on. But this substitution was never made and as such, water rates in India have never been fixed on scientific basis.

There existed a wide variety of systems for the calculation of water rates. There was multiplicity both in principle and in the rates for assessment in India (Central Water and Power Commission, 1955; P2). Some times, the value of the crop at maturity served as a rough guide in fixing irrigation charges. At other times, cost of providing water has been the overriding consideration of the rate fixing authority while calculating water rates. The productivity criteria for canals as evolved by the Government from time to time reflect this.

This issue of the economics of irrigation pricing was received the widest attention in the 20th century especially after Independence. The first deviation from the traditional past was made by Godgil. He referred to a number of economic benefits from an irrigation to the society as a whole and made a strong plea for a change in the productivity criterion to test the economic viability of an irrigation project. A distinction was brought out between the motives behind the private and the state investment. It was mentioned that "the investment policy of the state could be determined from a point of view broader than that of the direct net return on investment" (Godgil, D.R. 1948,

p.173). Accordingly, for the state investment in irrigation projects both the direct and the indirect benefits should be taken into account. Hence, he recommended that the measurement of economic benefits in case of all irrigation projects be made to include both the direct and the indirect benefits that accrue to the community and not merely the direct net return as advocated earlier.

The situation changed, during the period of Five Year Plans. Though, productivity criterion is not given up fully, it has not been adhered to strictly in practice. It has been realised that on the basis of existing rates of irrigation charges hardly any major work could be expected to be remunerative (GOI, 1952, pp.354-356). Large investments have been provided for improving the irrigation facilities throughout the country. Investments in irrigation have risen both in monetary and real terms as a result works of construction for the irrigation projects.

With regard to the water rates, whether water rate is a service charge or includes an element of tax. The Taxation Enquiry Commission (1953-54) had this to say : "the scale of water rates being largely dependent upon economic and other circumstances of the area commanded by the works it takes the character of a service charge in some areas and of a tax in other areas" (GOI, 1953-54, pp.252-55). According to this Commission, "broadly, the assessment of water rates may be regulated according to three different principles, viz., no loss and no profit, no profit and some loss and some profit and no loss. No single

principle can, however, be recommended for universal application. Generally, water rates must cover the maintenance charges, i.e., the policy must be no profit but also no loss. But to this there would be several exceptions. A policy of no profit and some loss would be justified in the case of an irrigation work for a dry land area which is being economically developed. On the other hand, a policy of some profit and no loss would be justified where an irrigation project has been provided for a fairly well-off area or where an old work existed from which benefit had already been derived and continues to be derived by cultivators in particular region.

In determining the water rate that is payable by those who take water, the principle would be, as indicated earlier, that the realisations from such a rate should at least cover the debt charges and over-head expenses on the project. Besides this principle, several other considerations are taken into account in fixing water rates. The more important of these are ; quantity of water supplied, value of crop grown, extent of benefit realised by the cultivator, and ability of the cultivator to pay.

Recently, the attention has shifted from the question of investment decision to that of recovery of cost. There has been thus two contradictory rules (GOI, 1957, P.43). The Planning Commission and the irrigation administrators have been emphasising the need for argumenting resources from irrigation. It is in this context that they have invariably recommended the upward

revision of water rates in the different Five Year Plans. Government in the states are also directed for imposition of betterment levies, compulsory annual cess on all lands in command area, agricultural income tax etc. The Plan documents have noted the extreme inadequacy of measures taken so far by the State Governments to argument irrigation revenues. This has been yet another view point advocating the case of keeping the level of irrigation charges lower. This argument has been based mainly on the under utilisation of irrigation potential created under the plan period. Thus, the Foodgrains Enquiry Committee (1957) recommended that concessional rate be charged for irrigation in regions where there was under-utilisation of potential (GOI, 1957, P.43). The Committee held that most important fact determining the use of irrigation water was the level of charges made for irrigation.

As irrigation confers benefits on the region served as a whole and as a part of its benefits flow back to the state through direct and indirect receipts on the account of increase land revenue, stamp duties, railway earnings, excise earnings, income tax etc., it also considered exclusive reliance on recovery of cost of project through water charges as unreasonable. Another views that `what is relevant a for fixation of water rates is not cost but benefits (National Council for Applied Economic Rsearch, 1957, pp.68-74). The only sound and justifiable basis for the irrigation rate should be the additional net benefit available to the cultivators from the use of water supplied. Since the demand for water depends on the willingness of the cultivators to make use of it, the amount of profits of the

actual net farm product available to cultivators can only be charged in the form of water rates. This amount of net profits to cultivators will depend from time to time, upon changes in land assessments, the prices of agricultural products, the excise duty imposed upon farm products, etc., This is the maximum which can be charged on the cultivators.

The N.C.A.E.R study arrived at some conclusions as considerations in fixing water rates. Water rates should be conducive to the most efficient utilization of water. The rates should offer sufficient inducement to the cultivator for the use of water. The rates should be such as to encourage the implementation of the national objectives or the state policy at the particular time in as much as the frame work for considering criteria for water rate is largely set by state policy. No single percentage of net benefit can be prescribed as water rate which can be fixed only on the basis of specific studies. In view of the need to allow the cultivator a share of the portion of the benefit the actual rates should in no cases exceed 50 percent of the additional net benefit to the cultivator. The actual charge could vary between 20% to 50% depended on nature of crop and supply of water. The minimum water rate is that which ensures the full use of the water rate. Till such time farming becomes commercial and farmers are able to grow the most valuable crop suited to the soil of his plot with requisite finance and facilities he should be charged on what he grows rather than on what best can be grown on his farm. As water rate has to be charged uniformly on all

cultivators without regard to the abilities of the individual cultivators and soil conditions the rate has to be so fixed as to enable even the lowest group of farmers to pay the charges without difficulty. The system of charging water according to volume supplied is not recommended as it involves a large initial investment for meters and supervisory staff. The principle of fixing water rates on the value of crop is not justifiable. Within the limit of the net additional benefit available to the cultivators and having considered the economic conditions of the majority of the cultivators, the rates should be fixed at a level that will bring in maximum revenues to the state. To attain the three fold objectives of furtherance of the social and economic policy of the state, maximization of net profits on the newly added farm products and realization of reasonable revenues for the state the actual application of the benefit criterion, should take into consideration several factors.

On the basis of additional net benefits arising from region to region and from canal to canal, the canal systems could be divided into three zones, viz., high, middle and low benefit zones and the percentage chargeable for each zone can be fixed variously within the zone by taking into consideration the following factors, nature of the soil, type of crop and the season in which the cultivation takes place, and volume of water required for each crop.

The basis of the crop rate system was the belief, right or wrong, that the level of individual rates according to the class of crops on which they were levied was enough to obtain a broad equality in the distribution of the burden of the tariff. The Maharastra Irrigation Commission 1962, studied that irrigation facility is a service and that it is reasonable that it should be paid for by the persons who take advantage of it and recommended that irrigation works as a whole should give an annual income which is equivalent to the annual cost there of and that the burden of providing irrigation should not fall, even in part, on the general tax payer (Government of Maharashtra , 1962; PP.67-75). The Commission considered the objectives of a satisfactory structure of water rates to be the total recoveries on account of water rates should not be less than the annual cost incurred by the state for providing the services. The water rate for a crop should be equitable in the sense that it should be related to the ability of the crop to bear it. Water rates should be so pitched as not to lay any irrigation potential unutilized on account of either the system of charging rates or the level of particular rates.

Further, the Commission indicated the following as the facts to be taken into consideration in formulating water rates for individual crops : The cost of irrigation water required by the crop, the level of average gross income obtained from the crop under the usual conditions of fertility, supply of manure, supply of water, level of efficiency of cultivation, and prices.

Prompted by the desire to improve the financial returns from the projects the Government of India appointed a committee to suggest ways and means of improving financial returns from irrigation projects under the chairmanship of Nijalingappa (GOI, 1964; pp. 1-31). The Committee considered, among other things, the criteria for fixing of water rates. In addition to this, they reviewed the studies made till then in this regard with specific reference to the study of the N.C.A.E.R, and the findings of the Maharastra Irrigation Commission. Consequently, the Committee felt that the best way of fixing water rates is to base it on the additional net benefit derived due to irrigation by the cultivators.

This was to be measured, according to the Nijalingappa Committee by the extent of net benefit after irrigation over the net benefit before irrigation. The Nijalingappa Committee recommended water rates equal to 25% to 40% of the additional net benefit derived per acre production of crops produced before and after irrigation, and those regarding per acre cost of production before and after irrigation. It is obvious that this committee tried a compromise of the recommendations of the N.C.A.E.R and the Maharastra Commission as the former has recommended water rate varying between 25% to 40% of the net benefit and the latter between 6% to 12% of the gross produce.

There were studies also available from demand side suggesting that, in order to wipe out the resulting deficit between the

construction cost of the modern irrigation project and the net return, a considerable rise in rates become necessary (Ansari, N, 1968, P. Vi). The study justified the demand side also and held that there was considerable scope for raising of rates on the basis of existing productivity. This study also showed a nominal relationship between the pitch of the water charges and the level of utilization as the latter depended more on a number of other technical and economic factors.

The problem of the relationship between the growth of irrigation facilities and cost recoupment principle was also studied by Second Irrigation Commission (GOI; 1972, P. 406). This study held that the benefit of irrigation is the benefit for the former. From the irrigation point of view, the water rate should be related to the benefit which irrigation confers rather than to the cost of an irrigation project, and felt that all factors from demand side need to be considered as criteria for fixation of water rates. These factors are: full utilization of available supplies, gross income of the cultivators and the farmer's capacity to pay for irrigation. The only factor that has been maintained from the supply side is the precaution against incurring losses. This study disfavored the idea of incurring losses in irrigation project.

A water rate structure which had for its basis the irrigation of only a single crop, namely, rice, is therefore no longer valid. In recent years great progress has been made in the development of agricultural technology. This has a bearing on

irrigation practices (GOI, 1972; P. 407 - 10). The value of irrigation is what it gives to the farmer in the form of an additional profit. The irrigation is primarily interested in the net gain from irrigation and to him the cost incurred in making water available is of little consequence. His willingness to pay for water varies in proportion to the gain that he expects from its use. From irrigation point of view, therefore, water rates should be related to the benefit which irrigation confers rather than to the cost of irrigation projects (GOI, 1972; pp.407-10). The irrigation requirements of various crops are governed by a number of factors such as climate, contribution from effective rainfall, if any, the level of the ground water table and the duration of the crop in the field. Because, the requirement varies not only from crop to crop but from the same crop grown in different seasons, such as the first, second or third crop of rice. Logically, therefore, the quantity of water supplied is also relevant.

Irrigation projects differ widely in their capacity to meet the irrigation requirement of crops, on projects with storage reservoirs it is possible, ordinarily to meet the full requirement of kharif crops although there may be some difficult in the pre-monsoon period. For rabi, the supplies vary from year to year. On projects with uncertain and fluctuating supplies, irrigation is less satisfactory and the irrigators have often to do with fewer or shallower waverings. Thus, there are areas which depend on tanks which fail in bad years. In such areas, proper crop planning and a resort to improved agricultural prac-

tices becomes difficult and in consequence yields are low. Adequacy and dependability of supply thus become important considerations in fixing irrigation rates. Where irrigation rates are kept unduly low, irrigators are, apt to use water carelessly and wastefully. On the other hand, a high rate may be burdensome to the cultivator and may discourage him from using available facilities. Such under-utilization results in less revenue to the Government and lower production for the farmer. Therefore, on canals which are under-utilized, a development rebate, which should be progressively reduced, would help to ensure fuller utilization. Needless to say, there will always be some lag in the utilization of water during the initial years after the completion of a project. Water rates can, to some extent, influence the cropping pattern in a project area. It is possible to discourage the growing of a particular crop in an area by fixing a high water rate for it. Effective regulation of cropping patterns through water rates, however, is not feasible. But even in fixing water rates for the different crops the state policy in respect of cropping needs to be kept in mind because some crops consumes more water than others. The crops which consume more water, are charged higher water rates than those that consume less water.

While fixing the appropriate rate, viz., the nature of the source, the duration of supply, the nature of the crop and the quantum of water required by crops, should be kept in mind (Government of Andhra Pradesh, 1973; P. 313). The committee recommended, a reduction in the real burden of water from as much

as 25% of gross produce or half of the net produce to about 2.5% of the gross produce due to increase in prices, increased profitability of irrigated crops and improving productivity, increasing cost of construction, repair and maintenance of projects.

Considering the above principles of water rate fixation, contrary pulls developed with regard to rate fixation. One emphasized the need to raise rates to recoup all the costs and the other pleaded for keeping down the level of rates to facilitate the full utilization of newly created capacity. As Ansari stated, there is need, from the long term point of view to cover the costs without subsidising irrigation by the State. Considering the above, the most rational water rate policy appears to be the one under which the water rates are fixed at a level such that the irrigation schemes do not impose a direct burden on the State exchequer.

Thus, water rates on the gross value of output from irrigated crop seems to be a reasonable measure. This variable is easily quantifiable in the regions and also suitable for regions where unutilisable capacity of irrigation exists. Other problems can naturally be solved only to a limited extent by a manipulation in the level of water rates. Manipulation of rates may be the best and effective course when based on the gross value of output.

RATES IN DIFFERENT STATES :

The system of irrigation water rates in various States of the country is as diverse as the culture and the people. Rates have been fixed considering a number of factors. Some times without any rational and objective considerations, they are seldom revised. Major factors leading to variation of water rates are : geographical unit, system of irrigation and crop and season. In states like Uttar Pradesh, Punjab, Haryana, Rajasthan, Bihar, Gujarat and Tamilnadu water rates are charged for actual areas irrigated under different crops, the rates varying with crops, regions and projects. In Orissa, there is a flat water rate per acre of land within the cultivable command area of an irrigation work payable to the state Government for supply of water whether used or not from an irrigation work (C.W.C.,1992, P.20). In Andhra Pradesh and other southern states, consolidated wet assessment is levied on lands registered as wet. Water rates are not being realized in Assam and Himachal Pradesh. In Nagaland and Meghalaya, there are no irrigation rates at present. In Sikkim, irrigation rates have not yet been finalized. There is thus, no uniform basis for irrigation charges in the country.

Rates for storage schemes are higher than those for flow or diversion scheme. Rates for lift irrigation from canals are generally higher than flow rates if arrangement for lifting is made by the government, but if the cultivators themselves make the arrangements for lifting water, the rates are lower than the flow rate. This is practised in Haryana, Madhya Pradesh, Maharashtra, Punjab and Uttar Pradesh.

In general, crop and season are two important factors in deciding the water rate structure. Water requirements of the crop and variation in seasonal availability of water are then the guiding principles. However, there is considerable diversity among states with regard to the weight given to them. Rates vary according to crop in almost all states. Water rates are generally higher for long-duration perennial crops such as sugar cane, as compared to short-duration crops. Sometimes the variation extends to the season also, as in Gujarat, Haryana, Maharashtra and Punjab, where different rates are charged for the same crop in different seasons. In Bihar and West Bengal rates are uniform for all crops in a given season, except for jute in hot weather in Bihar. In Southern state like Tamilnadu, the charge is levied according to the crop and season particularly for older irrigation systems. There are per-crop rates also for new irrigation projects.

Some times rates are kept low to induce farmers to use irrigation. This is prevalent in Gujarat, Madhya Pradesh, Orissa etc. Lower rates are charged in the initial years of commissioning of projects in some states. Similarly, location of the project is a factor in fixing a lower water rate if it happens to be in a drought-prone or backward area.

ASSESSMENT AND COLLECTION OF WATER CHARGES IN DIFFERENT STATES:

Mechanisms for assessment and collection of revenue are diverse. Assessment is generally based on area irrigated, except for Bihar, Orissa, and older systems of irrigation in Andhra Pradesh, Karnataka and Tamilnadu, where the water rate is a part of land revenue. In Bihar and also in some parts of West Bengal, Orissa and Madhya Pradesh, agreement rates are prevalent. In Orissa a compulsory basic rate is charged for rice in Kharif season from every cultivator whose land is served by the irrigation projects. For other crops of Rabi season, per crop rates are collected.

Reasonability for assessment and collection of revenue is shared by irrigation and revenue departments in the states, but there is no uniformity in this regard amongst the states.

Table 5.8 STATE-WISE ACCUMULATED ASSESSMENT INCLUDING ARREARS AND COLLECTION OF REVENUE

(RS. 10 MILLION)

STATE	PERIOD	ASSESSMENT	ACCUMULATED ASSESSMENT	COLLECTION INCLUDING ARREARS
Bihar	1984-85 to 1991-92	102.5	321.2	57.7
Gujarat	1980-81 to 1989-90	90.8	301.4	73.0
Haryana	1982-83 to 1991-92	105.2	192.7	98.9
Madhya Pradesh	1983-84 to 1991-92	195.3	722.0	137.3
Rajasthan	1982-83 to 1991-92	68.5	113.3	63.6
Uttar Pradesh	1980-81 to 1990-91	514.6	821.8	454.4
West Bengal	1980-81 to	30.2	173.3	8.8

Source : **Central Water Commission**, 1992, P.21.

The accumulated assessments, including arrears and collections, for the states of Bihar, Gujarat, Haryana, Madhya Pradesh, Rajasthan, Uttar Pradesh and West Bengal are given (see Table 5.8). They show out that substantial amounts remain unrealized as arrears, and that collection falls short of even current assessment in all the states.

WATER RATES FOR PRINCIPAL CROPS IN VARIOUS STATES :

The wide variety of systems and norms followed at present in fixing water charges lead to sharp variations in the levy from canal to canal in the same state apart from lack of uniformity among states.

Given the heterogeneity of the system of water rates prevailing in different states, it is extremely difficult to make a meaningful comparison of the levels of rates prevailing in those states. Strictly speaking, crop-wise rates cannot be compared in view of the fact that there is additional differentiation on the basis of the source of irrigation. While some states have adopted a simple system of charging water rates, others have adopted complicated ones which depend upon the source of irrigation, the nature of crops grown and the season of water supply (see Appendix V). There is a wide disparity in water rates for principal crops under flow irrigation in various states. In Gujarat, water rate ranges from Rs.234.16 to Rs.332.00 per acre of sugarcane crop. The rate in Maharastra is as high (Rs.100 to Rs.700) as against this. The prevailing water rate in all other states is less than Rs.100.00 per acre except, Madhya Pradesh, Karnataka and West Bengal. In the case of paddy, Madhya Pradesh, Maharastra, West Bengal and Gujarat are charging the highest water rates, (i.e., Rs.79.00 to 197.67; Rs.26 to 300; Rs.50 to 96 and Rs.44 to 100 per acre of water rates respectively), whereas it is around Rs.95 to75 in majority of the states including Andhra Pradesh. Orissa is charging the lowest rate of Rs.15.6 to3.95 per acre of paddy crop. Maharastra is charging rate of Rs. 72 to

120 per acre of cotton which is the highest in India. Madhya Pradesh, Gujarat and Uttar Pradesh are charging the highest rates of Rs.98.84; Rs.44.00; Rs.7.91 to 57.32 per acre of wheat respectively.

The water rate in Andhra Pradesh is fixed for wet and irrigated dry crop, irrespective of crop-wise fixation of water rates. For the single wet crop in Andhra Pradesh the rate per acre is Rs.60 to 40, whereas for 2nd and 3rd wet crop the rate per acre is the same as in 1st wet crop. For the irrigated single dry crop, the rate per acre is Rs.40 to 20, whereas for the 2nd and 3rd irrigation dry crops, the rate per acre is the same as in single dry crop. For Dufasal crop for 12 months period (i.e, Fasli Year) the rate per acre is Rs.120 to 80.

The prevailing water rates in respect of Paddy in Andhra Pradesh are lower when compared to those in Maharastra, Madhya Pradesh, West Bengal and Gujarat but higher than those in Punjab and Haryana (see Appendix-V). However, it is important to note that the existing water rate for paddy is higher in Andhra Pradesh than in Southern States of Tamil Nadu, Karnataka and Kerala. In the case of sugarcane, Andhra Pradesh is charging higher rates than Tamil Nadu.

It is also important to note that except Punjab, Kerala and Haryana all the states have revised the water rates in the mid eighties. Many of the states are not willing to revise the water rates mainly owing to political reasons.

WATER RATES IN ANDHRA AREA :

All cultivable lands in the Andhra area, are classified and registered in the land revenue accounts under three heads, viz., wet, dry and manavari lands. Classification of lands was originally made during the Revenue settlement operations on the basis of conditions on ground at the time of settlement and were liable to change during re-settlement operations. The rate of assessment was payable by the different categories of wet lands for different crops in the different crop seasons (Government of Andhra Pradesh, 1973, P.159). There are two categories of registered wet lands, viz., single crop wet lands, and double crop wet lands. Wet lands which in all ordinary season have an unfailing supply of water for one wet crop from a Government source of irrigation are registered as single crop wet lands. The rate of assessment varies with the taram of the wet land, and the settlement tract in which the land is situated and the classification of the source.

Wet lands, which in all ordinary seasons have an unfailing supply of water for two wet crops, are registered as double crop wet lands and are normally charged 1 1/2 times the single crop wet assessment are to be found only under class I source.

Irrigation cess or water rate is levied on dry lands for use of water for irrigation from a Government source and for irrigation of a crop other than the first crop on registered single

crop wet lands. In Revenue Parlance, water rates are levied on registered dry lands are called 'Thiruva Jasthi' and the irrigation cess payable for irrigation of second crop in a single crop wet land is known as Fasli Jasthi (Government of Andhra Pradesh; 1973, P.171). A second wet crop raised on such lands is liable to an extra charge which is ordinarily half the wet assessment. But when under any particular source of irrigation or in any particular locality a definite rate of charge has been prescribed for such crops. Extra charge will be levied at that rate and not half the single crop assessment. Thiruva Jasthi, in addition to land assessment on lands classed as dry when irrigated from a Government source would be imposed. Broadly speaking, the two systems for levying separate water rate in the Andhra area are : The differential water rate system and the fixed water rate system which were mentioned in preceding lines.

WATER RATES IN TELENGANA AREA :

In the Telangana area, all cultivable lands are classified and registered in the land revenue accounts under three heads, viz., dry, wet and garden. Wet assessment is levied on registered wet lands. The rates are fixed as maximum wet rates for a group of villages having identical conditions for the first crop. Wet lands are classified as single first crop wet (Ekfasala Abi), single second crop wet (Ekfasala Tabi), and double crop wet (Dufasala-ae). Wet cultivation is compulsory in all lands under flow irrigation sources. Flow irrigation wet lands are classified by settlement variously as single crop 'abi' single crop 'tabi' or double crop 'ae' (Government of Andhra Pradesh; 1973,

P. 167). Abi crop is deemed to be the first crop and the tabi crop as the second crop. If flow irrigation water is taken for double crop wet cultivation in a single crop wet land throughout the year full double crop wet assessment is levied. In case of lands classified as double crop wet lands, full single crop wet assessment is levied for abi and half the abi assessment for the tabi crop. A differential water rate system more or less same as in Andhra Area, is in force in Telengana area also while charging a dry land for use of water from a source.

WATER RATES IN ANDHRA PRADESH SINCE 1956 :

Resettlements were abandoned in Andhra in the year 1939 and in Telengana in the year 1953 as a matter of state policy. Instead of revision of assessment on wet and dry lands periodically through resettlements, thereafter, the rates of assessment came to be revised from time to time.

At the time of formation of the State of Andhra Pradesh, the settlement or resettlement rates, as the case may be, existing as standardized by the Act of 1952 where the rates of assessment applicable in Telengana area were in force till the Government of Andhra Pradesh enacted the Andhra Pradesh Land Revenue Additional Assessment (G.O.No.168, dt.31.01.1963). In so far as, the Andhra area of the Andhra Pradesh was concerned, the assessments levied under resettlements continued in force till 1956. Land assessment of different settlement tracts, and districts having been settled at different times the rates of assessment obtaining in

different parts of Andhra area where not uniform in its incidence in as much as the continuous rise in prices during the period of resettlement had resulted in higher commutation rates being adopted in the case of the districts resettled at a latter date than in the case of those settled earlier. The result was that the pitch of assessment varied widely from district to district.

Thus, in Andhra Pradesh, prior to 1986 land revenue was being levied on both dry and wet lands at specific rates and the charge for use of water from a Government source of irrigation was levied in the form of consolidated wet assessment, in respect of lands registered as wet in revenue records. As this rate was said to notionally comprise an element of land revenue and a charge for water, no separate charge was required on single crop wet land for raising first wet crop. For raising second or third wet crop on registered single crop wet land and for irrigating a dry land, water cess was leviable. In respect of unirrigated dry land, only basic land revenue was levied besides land/local cesses.

The water sources were divided into the following 5 classes: perennial rivers, tanks giving water for not less than 8 months, minor river channels and rainfed tanks giving water for 5 months and more, spring head and other channels giving water for 3 months and more and all irrigation under jungle streams with a precarious water supply as well as rainfed tanks giving water for less than 3 months.

The rates which were standardized in 1956 were enhanced in 1967 with effect from 1st July 1962, in 1975 with effect from 1st July 1974 and in 1986 with effect from 1st July 1986.

Substantial modifications for the basis, rates and collection of water tax have been made with effect from 1st July 1986 through the Andhra Pradesh Water Tax Act, 1988. All lands, were regarded as dry and separate land revenue was abolished.

The Act also contemplated recovery of water tax in respect of lands irrigated by category I and category II sources only. For this purpose, all major and medium irrigation projects are to be regarded as category I while other government sources which supply water for not less than 5 months in a year belong to category II. Further, water tax is chargeable with refeence to the nature of wet crop, irrigated dry and dufasal crop. The rates of water tax ranged from Rs.40 to Rs.120 in respect of lands irrigated by category I sources and Rs. 20 to Rs.80 in respect of category II sources 54.16 lakhs of acres of land is irrigated by category I sources and 14.41 lakhs acres of land is irrigated by category Ii sources, while 15.85 lakhs acres are irrigated by sources supplying water for less than 5 months.

The procedure of assessment of water tax is analogous to that of land revenue in vogue earlier. The basic record for computation is village account containing details regarding survey number, extent of land, pattadar, nature of crop, source

of irrigation etc. The demand which is initially worked out annually by the Village Administrative Officer is finally approved by the Jamabandi Officer. The tax is collected in two instalments by the Village Administrative Officer and remitted into the treasury. These remittances are reconciled by the Mandal Revenue Officer with the treasury figures.

Revenue realised as Water tax showed that not even 15% of the maintenance cost was realised.

Table - 5.9 REASONS FOR VARIATION OF WATER TAX AND RECEIPTS AS ON 1994-95

(RS. IN LAKHS)

REASON	LOSS
1. Adoption of incorrect wet aasessment rate	28.21
2. Short levey of water tac due to incorrect categorisation	16.07
3. Short assessment of water tax due to adoption of incorrect pre-revised rate	55.03
4. Incorrect implmentation of the provisions of the Andhra Pradesh Water Tax Act, 1988	8.97
5. Incorrect grant of remission	88.20
6. Water tax in terms of court's order was not correctly interpreted	9.61
7. Non-determination of water charges may result in non-revocery of royalty in respect of water supplied for non-irrigational use.	109.50

Source : **Government of Andhra Pradesh**, 1996, No.2, P.81.

The reasons for large variation between budget estimates and actual receipts were attributed by the department to reintroduction of Village Administration (see Table 5.9). Nontheless, the receipts recovered under Water Tax are very less when compared to operation and maintenance costs.

CONCLUSION:

To sum up, the approaches mentioned here involve radical changes in the way irrigation systems are organised and managed

even as it requires users to pay substantially higher prices for the water they use. Judging by the reported trend in revenues the impact of these revisions on users of public irrigation systems has not been significant nor have they led to any improvement in the financial performance of these systems. These changes are essential and important constituents of any effort to improve public finances generally and that of the State Government in particular.

There were several systems of charging irrigation water in different parts of the country during the British administration While the British tried to reationalise the high water rates by searching for principles of fair returns to investment by both the government and farmers, the present Independent India does not seem to have any rational economic principles on which to fix low rates.

APPENDIX-V-i

COMPARATIVE WATER RATES FOR PRINCIPAL CROPS UNDER FLOW IRRIGATION I DIFFERENT STATES

(RS. PER ACRE)

STATE	DATE OF ENDORSEMENT	RICE	COTTON	WHEAT	SUGARCANE
1	2	3	4	5	6
Andhra Pradesh	1st July 1986 Wet crop 1st crop	60 to 40	60 to 40	60 to 40	60 to 40
	2nd or 3rd	-do-	-do-	-do-	-do-
	Irrigated dry				
	1st Crop	40 to 20	40 to 20	40 to 20	40 to 20
	2nd or 3rd	-do-	-do-	-do-	-do-
	Dufasal crop in fasli year	120 to 80	120 to 80	120 to 80	120 to 80
Assam	No water rates are inforce at present				
Bihar	-	-	-	-	-

NOTES:

1. Referring to the principle according to which the water cess was to be imposed, Mr.Taylor observed that it was simply a test by which to determine whether the assessment already levied was sufficiently high, or whether additions could fairly be made to the demand. The great object was to ascertain what the land actually yielded when supplies with anicut water, and if it were found that the amount of gross produce and the generally improved circumstances of a village justified the levy of **teerwa jasty**, to assess it accordingly that is to make an addition to the collective or joint rent of the villages, the distribution of which should be left to the **Ryots** and themselves. the water tax being thus determined on general data, and its amount discretionary and blended with the assessment of the village can not be represented aa a given sum. The irrigated products may be viewed under two classes, viz., such as a large quantity of water to bring them to maturity, and those for which a moderate supply will suffice. The former includes paddy, sugarcane, and coconut plantations; the latter, turmeric, onions, and all ordinary garden produce. The quantity of water necessary to bring these products to maturity varies with the class to which they belong as above defined, all in the same class requiring about the same quantity of water. To tax a given extent them, with reference to the product under this view is the same thing as taxing it with reference to the quantity of water used.

The true mode of taxing irrigated land is that which has the sanction of immemorial usage, viz., to fix the assessment on a

joint consideration of the quality of the land and of the quality of the irrigation. Two scales of rates for the different soils of a District would thus be fixed, one for lands enjoying a full and certain supply of water, the other for lands, the irrigation of which is imperfect. This rule applies equality to tanks and river channels, Government of Madras, 1858, pp.166-67).

2. The object of the Select Committee Report (1879) was to provide a formal criterion for allocating loan funds among the various canal projects. However, in insisting that a productive work should yield annually a given money rate of return which, besides meeting the annual working expenses, at least equaled the debt service charge, the committee was also pleading for the use of the rule "full-cost pricing in the sale of canal waters to the various classes of operators (**Report from the Select Committee on East India**), Public Works, 1879, pp.iii to xxi).

3. Under the raiyatwari system, all landholdings are registered for revenue purposes. Every plot of land on which land revenue is payable is registered in the name of an individual who is responsible for the payment of the land revenue ; he is issued with a document, a patta, describing the lands registered in his name. The man who pays the revenue on the land in effect its owners : The government argued :

> Under the Rayatwari system every registered holder of land is recognised as its proprietor and pays direct to Government.

He is at liberty to sub-let his property, or to transfer it by gift, sale or mortgage. He cannot be ejected by Government so long as he pays the fixed assessment. The ryot, under this system, is virtually a proprietor on a simple and perfect title, and has all the benefits of a perpetual lease without its responsibilities, in as much as he can, at any time, throw up his lands, but can not be ejected so long as he pays his dues : he receives assistance in difficult seasons, and is not responsible for the payment of his neighours.

If the Pattadar defaulted on his land revenue, the Government sold as much of his land as was enough to recover the dues. The Pattadar was allowed to relinquish part or all of his land so that he would not be liable to pay the land revenue due on it, provided, first, that he applied for permission to do so early in the season so that the land was available to others. Anyone could apply to take up unoccupied lands, though mirasdars and residents of the village were given first refusal (Dharma Kumar, 1975, pp.230-231).

Also, the favourable form of tenure...with it heritable rights of sale and purchase of land, although there were differences of opinion regarding its origin and the scope of the rights involved (Dharma Kumar, 1992, pp.14-15).

CHAPTER - VI

PRODUCTIVITY, PRICES AND WATER RATES IN ANDHRA PRADESH

INTRODUCTION

The supply of water to a number of farms is the actual service rendered by the government when it constructs an irrigation project. It might, therefore, be expected that the benefits of this operation would be measured by the prices which the farmers would be willing to pay for the supply of the water. To the extent that conditions are favourable for good crop with irrigation, it is likely that a "surplus" of resources will be generated which benefit some combination of farmers, managers, the government, and the consuming public. Incomes are increased, more resources are available, more taxes can be generated, and more food can be brought at lower prices. Wwhere irrigated agriculture is profitable for water users, they have more stake in the activity and are likely to be willing to cooperate in management that pays (Uphoff. N, et. al., 1991, p.90). Also, managers can make a more credible claim on government resources for systems' operation and maintenance budgets, and regimes will be more willing to invest in operation and maintenance. The profitability of irrigation affects the willingness of farmers and government to invest in its improvement. But there are strong reasons which preclude so simple a measure. If the farmers had to pay as much for it as it was worth in terms of

additional output, there would be no incentive for them to engage in the long and back-breaking task of bringing the irrigable acreage into intensive cultivation. Thus, a direct measure of the economic worth of the water supply could not be predicated on the actual revenues, but rather on a hypothetical computation of the maximum amounts which the farmers would be willing to pay if they were perfectly rational entrepreneurs (Eckstein, Otto, 1958; P.197). There are two categories of direct farm benefits. Firstly, increased "family living" including the home-grown products consumed by the family, and the higher level of other perquisites such as the farm dwelling. And secondly, increased cash allowances for family living expenditures, the increased in cash income after deduction of all production expenses. Thus the direct economic returns to irrigation in India can be focused on productivity, prices and water rates. Therefore the need for estimating the share of water rates to the gross value of output generated by investment in irrigation is worth studying[1].

Because of lack of comparable data relating to cost of cultivation and all other deductions for all the previous years compiled on a uniform basis, it is felt that it would be convenient to compare the gross value of yield of rice per-acre by annual average wholesale prices prevailing at the chief market centres.

It is important to keep in mind the limitations of such estimates. Firstly, the method of estimation implies shifting

land out of rainfed cultivation into irrigated cultivation. To the extent that irrigation brings new lands under cultivation, this approach under states the total benefits of irrigation. Secondly, the aggregate data for irrigated area used in these equations covered wide range of gross irrigated area. These estimates indicate only direct production effects evaluated domestic prices, and do not attempt to include additional benefits from employment and, stimulation of other economic activities or other indirect factors.

The productivity differential reflects the combined effects or irrigation, complementary inputs, technology, and farm labour on output per-acre. Thirdly, rice is the most important crop raised in the state accounting for more than 50% of the total cropped area and for 73.4% of the total irrigated area in 1989-90 (Government of Andhra Pradesh, 1990-91, pp.1-13). Thus, irrigated farming in the State is represented almost by a single crop, viz., rice. And finally, the four delta districts of East Godavari, West Godavari, Krishna and Guntur in Coastal Andhra, Kurnool in Rayalaseema and Nizamabad in Telangana region have the largest proportion of irrigated area under the canals. Therefore, these six districts have been chosen for a study of the variations in the productivity, prices, and value of output of rice per acre in relation to the incidence of water cess.

TRENDS IN PRODUCTIVITY :

The benefits of irrigation are well recognised, particularly by farmers. Reliable and timely water supplies enable farmers to

get increased yields from the existing crops. The yields per acre of rice generally showed an upward trend in all the major rice-producing districts in the State. There were differences in the yield estimates of ryots and estimated from Government experiments. For example, the average produce of paddy per acre was estimated in Krishna district in 1869 at 2421 lbs (or 1099 kgs.) valued at Rs.44 and 2574 lbs (or 1169 kgs.) of straw valued at Rs.12 and the total of Rs.56. The data on yield per acre of rice (in Madras Presidency of Andhra Pradesh) of East Godavari, West Godavari, Krishna, Guntur, Kurnool and Nizamabad were presented in below table.

Table - 6.1 **Productivity of paddy per acre (in quintals) of some irrigated districts in Madras Presidency - 1918-1947**

(1b = 1 Pound = 0.454 kgs. per acre)

YEAR	DISTRICT				
	EAST GODAVARI	WEST GODAVARI	KRISHNA	GUNTUR	KURNOOL
1918-19	9.1	8.6	8.2	7.3	N
1927-28	9.1	9.1	8.2	8.2	7.3
1939-40	8.0	7.4	6.6	8.2	7.1
1940-41	8.4	8.1	8.0	8.6	7.9
1946-47	8.7	7.8	7.6	7.0	6.3

Source : **Agricultural Census Reports of different years, Madras.**

The yield per acre of rice in Madras Presidency slightly decreased when compared to the years 1918-19 to 1946-47 (4.4%) (see Table 6.1). This was mainly because of the inconsistency in estimates of the yield of irrigated lands.

The three yearly moving average, variations in yield per acre of rice and the index numbers of productivity for recent years are shown in Table 6.2 and 6.3, while the data on yield of rice per acre for the period 1955-56 to 1996-97 are shown in Appendix VI. However, the trend in productivity raised much larger extent during the period 1968-69 to 1996-97 in delta areas, in East Godavari, West Godavari, Guntur and Krishna. The yield per acre of rice increased 40%, 34%, 54% and 50% respectively, while in Kunrool it was 54%, but in Nizamabad it increased only 8.2%. This trend was mostly influenced by rainfall and irregular irrigation.

Source : Based on data given in **Annual Season and Crop Reports** of Andhra State & Andhra Pradesh and **Statistical Abstracts of Hyder**abad State, in different years - D.E.S, Hyderabad.

There are some limitations in the data on yields including the non-availability of separate figures of yield for delta and upland areas. Only the average district yield rates are available. Thus the decrease in some years in the average yields of some of the delta districts might have occurred in the upland areas, while that of the delta area might have remained relatively constant.

PRICE TRENDS:

There has been an enormous increase in the general price level in Andhra Pradesh as well as in the country as a whole. Two kinds of price effects are there. Output remaining the same, the per-unit price increased. Secondly, the output per acre had increased. Therefore, the value of output per acre had increased in terms of rupees per quintal.

Table 6.4 **Farm harvest prices of Paddy per-acre (in quintals) in some irrigated districts of Madras Presidency, 1918-1947**

Source : **Agricultural Census Reports of different years, Madras.**

The price of paddy per-acre (in quintals in some irrigated districts of Madras Presidency during the period 1918-1919 to 1946-1947 was increased by 33%. During the period 1970-71 to 1979-80 it was increased by 33% and in the period 1980-81 to 1997-98 it increased by 66% (See Table 6.5).

There have been significant variations in the productivity of rice over the past two to three decades, except in the case of Nizamabad district. Consequently, the gross value of output of rice per acre, rose enormously mostly under the impact of rising prices.

TABLE - 6.5 VARIATIONS IN THREE YEAR MOVING AVERAGE OF WHOLE-SALE PRICES OF RICE AND INDEX NUMBERS. (in Rs. per Quintal) - 1955-56 to 1997-98.

YEAR	MOVING AVERAGE	INDEX NUMBERS

TRENDS IN WATER RATES:

The initial settlement of land revenue assessment was completed during the last quarter of the 19th century. In theory, it was sought to be appropriated by way of wet assessment nearly 50% of the net value of agricultural produce. The cost of cultivation was deducted from the gross value for arriving at the net value. But then, the elaborate procedures followed and the liberal concessions allowed in the process of valuation of the produce reduced the effective incidence of the land revenue including assessment to less than 1/4th to 1/6th of the gross produce (Government of Andhra Pradesh, 1973, P.275). For instance, the average price prevailing in 20 non-famine years preceding the settlement was generally adopted as the basis for calculation. Since the prices adopted were wholesale prices prevailing in market centres, a deduction of about 15% was allowed from the wholesale prices towards profits of merchants, and another deduction of 10 to 25% was allowed towards vicissitudes of the season.

The project water rate charged in delta areas of East Godavari, West Godavari, and Krishna remained at Rs.5 per acre till 1931-32 (G.O.No.562, dt.2.08.1894), when it was enhanced by 25% to Rs. 6.25 per acre. Subsequently, there was no revision in the water rates till 1956-57 (Government of Andhra Pradesh; 1973, P.276). Since then the project rate or water-cess was increased in stages by 25% in 1956-57 (G.O.No.982, dt.27.05.1957), another by 25% in 1957-58 and another 50% in 1962-63 (G.O.No.168, dt.31.01.1963), (see Table-6.6). Further, it was enhanced by

100% in 1975-76 (G.O.No.412, dt.22.03.1975), and in 1986-87 (G.O.Act-11 of 1988, dt.24.08.1989) a uniform water rate was fixed which was enhanced by 100% (see Table 6.7). Major and medium irrigation works were divided into category I and II. Any source of irrigation coming under Major and Medium irrigation projects shall come under category-I. Sources other than major and medium irrigation sources shall come under category-II. The Government of Andhra Pradesh has further enhanced the water rate through ordinance by 233% in 1st July, 1996 (Government Ordinance, dt.01.07.1996).

Almost a similar trend is evident in the case of Kurnool District also, in the case of which, average consolidated wet assessment has been taken for analysis. There was no enhancement

of the rates of wet assessment at the time of resettlement and the average rate per acre for wet lands in Kurnool District was Rs.6-88 till 1955-56, when it was increased by 1/2 anna in a rupee. The rate was enhanced by 18 3/4% in 1956-57 and again by 18 3/4% (G.O.No.982, dt.27.05.1957), in 1957-58 and by 1962-63, the rate was doubled to Rs 14-20 which is also the current average wet rate of assessment (G.O.No.168, dt.31.01.1963) (see Table 6.8). Further, it was enhanced to 10% (i.e; Rs.15), in the year 1965-66 and by 100% in 1975-76,(i.e, Rs.30) (G.O.No.412, dt.22.03.1975). During the year, 1986-87, a uniform water rate was fixed throughout the state (G.O.Act-11 of 1989, dt.24.08.1989). Wet assessment was abolished and water rate by 100% (i.e Rs. 60) (see Table - 6.6). It was further enhacned by 233% in 1996-97 (Government Ordinance 01.07.1996) (i.e., Rs.200/- per acre, per single wet crop under category-I). This enhacement was taken place owing to the mounting cost of capital for development irrigation which mentioned by government in the ordinance.

For Nizamabad District also average consolidated rates, have been considered. At the time of the formation of Andhra Pradesh the rates of land revenue were already considerably higher in the Telengana districts as compared to the remaining districts of the state and therefore, as part of the programme of rationalisation of land revenue assessment in the state, only a small enhancement of about 30% was effected in Nizamabad and other Telengana districts as against 100% in wet assessment in the Andhra region (Government of Andhra Pradesh, 1931; P.277). The average wet rate of assessment in Nizamabad district was Rs.10.60 till 1952-53 when it was enhanced by one anna in a rupee, to Rs.11. There after the average rate was again enhanced to Rs.14-24 in 1962-63 (see Table 6.10). During the year 1966-67, average rate was enhanced by 5% (i.e., Rs.15) and in the year 1975-76, it was 100% enhancement (i.e., Rs.30) (G.O.No.412, dt.22.03.1975). Further in the year 1986-87 (G.O.Act 11 of 1988, dt.24.08.1989) a uniform rate was fixed instead of consolidated assessment, and it was enhanced by 100% (i.e., Rs.60.00) (see Table - 7.11). Further it was enhanced by 233% (i.e., Rs.200/- per acre).

SHARE OF WATER RATES IN GROSS VALUE OF OUTPUT:

The proportion of Government assessment to the gross produce was estimated by the settlement calculations at 6.3%, taking the value of the gross outturn at 50 crores of rupees, and land revenue at 3.16 crores. They have excluded from land revenue 1.37 (2.9%) crores at being water charge and not forming part of land tax proper. Including amount, the proportion was 9.2% (S.S.Raghavaiyangar, 1893, pp.112-113). In these calculations, however, the outturn of favourably assessed inam lands and of Zamindari lands which pay to government a smaller revenue than ryotwari lands, has been included.

Taking the ryotwari lands alone, the average rate of assessment for wet lands was Rs.5/- per acre and for dry lands Rs.1/- per acre and these rates are between one-fourth and one-fifth and one-fourth and one-sixth respectively of the gross outturn according to settlement calculations after deducting from the average outturn 16 2/3% in the case of wet and 25% in the case of dry lands as allowance for vicissitudes of season. The average

yield, the cultivation expenses and the water rape per acre of Madras Presidency are given below.

Table 6.12 **Statement showing the average yield, the cultivation expenses and the rent per acre of Madras Presidency-1861 to 1880**

Water rate	1	3	2	5	1	9
Ratio of water rate to the produce	14.87			20.08		
Former's profit	3	9	11	10	12	7

Source : Based on S.S.Raghavaiyangar's **Memorandum on the progress of the Madras Presidency** : During the last fifty years, 1893, Appendixes - Table -3, P.cxlvii

The data shows that the half of the value of produce were remaining with the farmers and the rest were taxed (see Table 6.12). The share of water rate to the gross value of output was more than one-sixth in dry areas, while in wet areas it was one-fifth. The ratio of water rate to the produce was 20.08. While irrigated dry the ratio of water rate to the produce was 14.87. The gross value of output of rice per acre (in Rs.) in principal districts of Madras Presidency are given in below table.

Table 6.13 Gross value of rice per acre (in Rs.) in some irrigated districts of Madras Presidency - 1918 to 1947

YEAR	DISTRICT

1946-47	80.04	66.30	68.40	65.10	66.78

Source : **Agricultural Census Reports** of different years, Madras.

The data shows that the gross value of output during the period 1918-19 to 1946-47 in the districts East Godavarai, West Godavari, Krishna, Guntur, Kurnool and Nizamabad increased by 30%, 30%, 22%, 9% and 22% respectively (see Table 6.13). For Nizamabad, the data on yeidl and prices of rice was not available in those years. The share of water rates to gross value of output are given below.

Table 6.14 Share of water rates to Gross value of output of rice per acre in some irrigated districts of Madras Presidency 1918 to 1947

YEAR	DISTRICT				
	EAST GODAVARI	WEST GODAVARI	KRISHNA	GUNTUR	KURNOOL

1940-41	14.0	18.0	15.0	17.4	15.0
1946-47	8.0	9.5	9.2	9.6	10.3

Source : Computed from Table 6.6, 6.8, 6.10, and 6.13

The Project water rate increased by only 150% since 1900 as against a rise of 750% to 1000% in the gross value of output per acre. As a result, the incidence of the project water rate fell to less than even 1/4th of its former level in the delta districts. The average wet assessment of Kurnool district formed about 21% of the gross value of rice per acre around the year 1900 (Government of Andhra Pradesh, 1973, pp.275-278). It is generally assumed that on an average, water charge constitute about 2/3rds of the consolidated wet assessment. Thus, the comparative incidence of average wet assessment in delta districts of that time would have been of the order of 15% to 16%. The relatively lower incidence, despite higher rates of assessment, is attributable to higher yields in the delta region (see Table 6.14 and 6.16). By 1946-47, the average water rate to

gross value per acre in Kurnool District declined to 10.3% and it further fell to 3.0% by 1968-69 (see Tables 6.14 and 6.16). During the year 1978-79, the average water rate to gross value per acre of output of rice increased to 30% and in the year 1989-90, it was 3.6% (see Table 6.16). Whenever enhancement of water rate was taken place, the share of water rate is fluctuating with gross value of output. The same trend was maintaining till 1996-97.

The average wet rate in Nizamabad district was formed about 9.6% of the gross value per acre in 1946-47 but it ultimately declined to 2.5% by 1968-69, owing to increased output and prices. The considerable fall in the proportion of average land revenue or water rate between 1942-43 and 1968-69 in Nizamabad district was not only due to increase in the price levels and stagnation in the rates of assessment but also due to a significant increase in the productivity per acre following development of cultivation in the Nizamsagar area (see Table 6.15). The average rate in relation to gross value, further 1985-86 by 2.0% and 1.4%. But in the period 1986-87 to 1989-90, it was increased to 2.8% and 3.3% (see Table 6.16). This has further increased by 4.7% of gross value due to output enhancement of water rate in 1996-97.

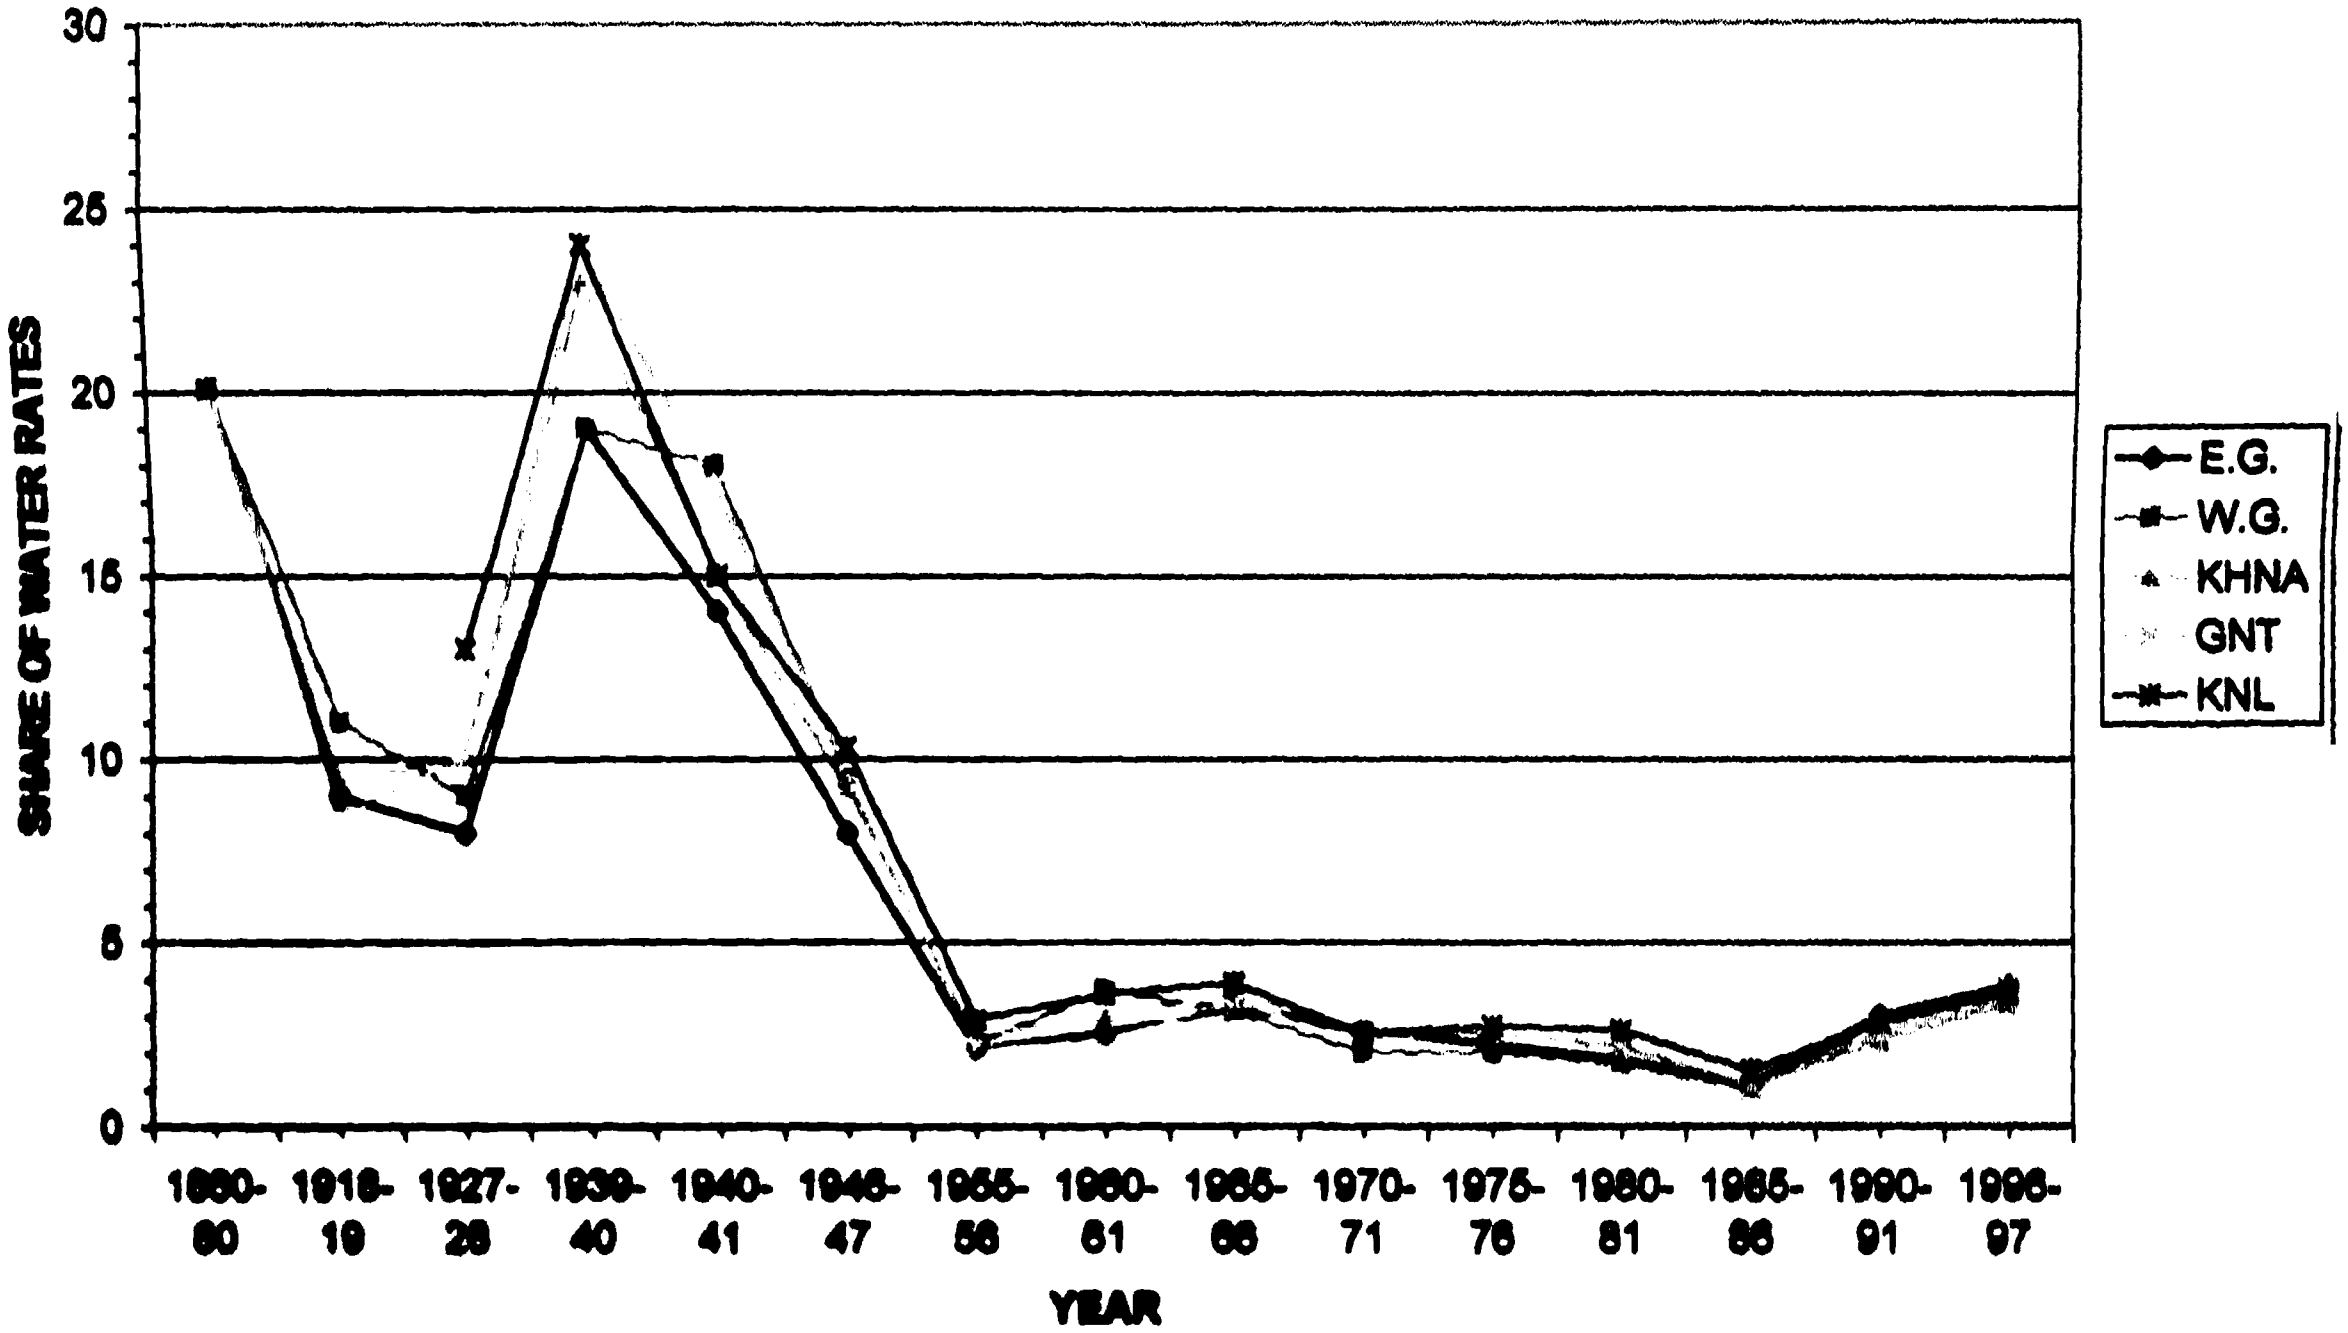
Source: Computed from Tables 6.12, 6.14 and 6.16

In general, Water cess formed about 11% to 9% of the gross value of Rice per acre towards 1900, while it had come down to about 9% to 8% by 1946-47 (see Table 6.14). As a consequence in the value per acre as compared to the water rate levied, water cess further declined as a percentage of gross value to about 2% to 3% by 1955-56. Between 1956-57 and 1963-64, there had been improvement in this percentage i.e. from to 3% to 4% in the wake of periodic enhancement of the water rates. But once again after 1963-64 the downtrend resumed till the proportion of water cess to the gross value of output per acre dwindled to less than 3% by 1968-69. Further, 1% level in 1985-86, 3% level in 1989-90, and 3.8% in 1996-97. i.e., to the same levels as obtaining prior to the enhancement of water cess in 1957-58. (see Table - 6.16). The gross value of output per acre of rice increased throughout the period (1955-56 to 1990-91) by 35 times, whereas water rates

SHARE OF WATER RATES IN GROSS VALUE OF OUTPUT OF RICE IN SOME IRRIGATED DISTRICTS OF A.P.



increased only 8 times (see Figure 6.1). Thus, the low water rates in relation to gross value of output may be low assessment of water rates, while benefits are well recognised owing to the irrigation development.

SHARE OF WATER RATES IN COST OF PRODUCTION :

The concept of total cost is used as synonymous with cost C2 and this includes the expenditure incurred on human labour (owned, exchanged and levied), bullock labour (owned, exchanged and levied), seed (owned, exchanged and purchased,) organic manure (owned and purchased), fertilizers, pesticides, land revenue, cesses and taxes, irrigation charges, depreciation, interest on working capital, interest on fixed capital, rend paid for leased-in land, rental value of owned land and others miscellaneous expenditure. The cost of expenses of paddy during the Madras Presidency (settlement calculations - 1861-1880) was Rs.9 - 8 - 9 per acre for wet crops and for irrigated dry it was it was Rs.3 - 3 - 10 per-acre (see Table 6.12)

The costs of cultivation of paddy in one acre has gone up by six times between 1971-72 and 1989-90. The rising levels of yields have slowed the rise in costs per qunital of paddy rose less than twice while that per acre rose by nearly three times. Increases in yields and gross value of output have occurred in the case of irrigated crops. Costs of cultivation in the State have been higher than in other states. Irrespect of paddy it is higher than in Punjab and Uttar Pradesh.

TABLE - 6.17 WATER RATES AS PERCENTAGE OF COST OF CULTIVATION

YEAR	TOTAL COST OF PRODUCTION (IN RS.PER ACRE)	WATER RATES AS % OF COST OF PRODUCTION.
1971-72	597.70	2.5
1972-73	547.21	2.7
1973-74	695.87	2.2
1974-75	909.49	1.7
1975-76	808.05	3.7
1976-77	1011.65	3.0
1977-78	1096.96	2.7
1978-79	1248.06	2.4
1979-80	1273.44	2.4
1980-81	1576.74	2.0
1981-82	1556.64	2.0
1982-83	1790.00	1.8
1983-84	2142.19	1.4
1984-85	2332.19	1.3
1985-86	2466.03	1.2
1986-87	2591.13	2.3
1987-88	2894.87	2.1
1988-89	3233.89	1.9
1989-90	3210.89	1.9

Source : From 1971-72 to 1983-84 data given in **Cost of Cultivation in Principal Crops** - 1990 D.E.S., New Delhi & From 1984-85 to 1989-90 data given in **cost of cultivation Cell, A.P.A.U., Rajendranagar, Hyderabad.**

The per acre total cost of production of rice during the year 1971-72 was Rs.597.70, while the water rate was Rs.15 per acre in the same year, which was 2.5% of total cost of production (see Table 6.17). From the period 1971-72 to 1976-77, the cost of production and water rates per acre were increasing tremendously. During the period 1971-72 to 1976-77 the cost of production, and water rates per acre increased by 41% and 17% respectively. But during the period 1977-78 to 1989-90 the total cost of production of Rice per acre was increased to 66% while water rate descreased to 30%. It is clear from the table 7.15, that the cost of production increased by 5 times during the period 1970-71 to 1989-90, whereas the water rate share in the cost of production has been descreased to 25%.

CONCLUSION:

To conclude the analysis reveals that, the benefits from irrigation are high and economic rates of return from irrigation are low. The productivity and prices of rice were raised much larger extent in the districts of East Godavari, West Godavari, Krishna, Guntur, Kurnool and Nizamabad. The ratio of water rate to gross value of output was 20.08 during the period 1861-1880. It has been decreasing continuously (i.e., in 1918-19 it was 11%, and in 1946-47 it was 8%, and in 1966-67 it was 2.6%, and in 1995-96 it was near to 1%).[2]

The gross value of output per acre of rice increased throughout the period by 35 times (1955-56 to 1990-91). Whereas water rates increased only 8 times while the cost of production increased by 5 times during the period 1970-71 to 1989-90. Whereas water rate share in cost of production decreased by 25%. Thus, the low water rates in relation to gross value of output may be low assessment of water rates, while benefits are well recognised owing to the irrigation development.

Source : Data given in **Annual Season and Crop Reports of Andhra** State & Andhra Pradesh and **Statistical Abstracts of Hyderabad** State, in different years - **D.E.S, Hyderabad.**

NOTES:

1. Before formation of Andhra Pradesh, the parts of Andhra Pradesh was under regime of Madras and Nizam governments. For that reason, the data from 1955 onwards are taken for this analysis. To obtain data on productivity and prices of rice, Agricultural Census Reports and Season and Crop Reports of different years are well worth. For water rates, the data are taken from Government orders for fixation of water rates in different years.

2. As the Irrigation commission (1992) had suggested that water rates should be fixed at around 5% of gross income for food crops and 12% for cash crops. At present, the actual gross receipts per acre of area irrigated by major and medium projects is barely % of the estimated gross output per acre of irrigated area, and ess than 4% of the difference between output per acre of irrigated and unirrigated areas. Since the gross receipts include several items other than water charges and cesses levied on irrigated land-accounting for about 27% of the total receipts during the early 1980's. In Andhra Pradesh, during the year 1992-93, the items other than water charges and cesses levied on irrigated land account for about 0.55% i.e., below 1% (Land Revenue Drainage cess, other receipts from major and medium, minor were Rs.7628 lakhs, while total gross value of agricultural production was in Rs.13,77,172 lakhs). When considering items other than water charges and cesses levied on irrigation land, the incidence of irrigation charges per se must be considerably low (Government of India, 1992, pp.30-71).

CHAPTER - VII

SUBSIDIES IN IRRIGATION

Introduction :

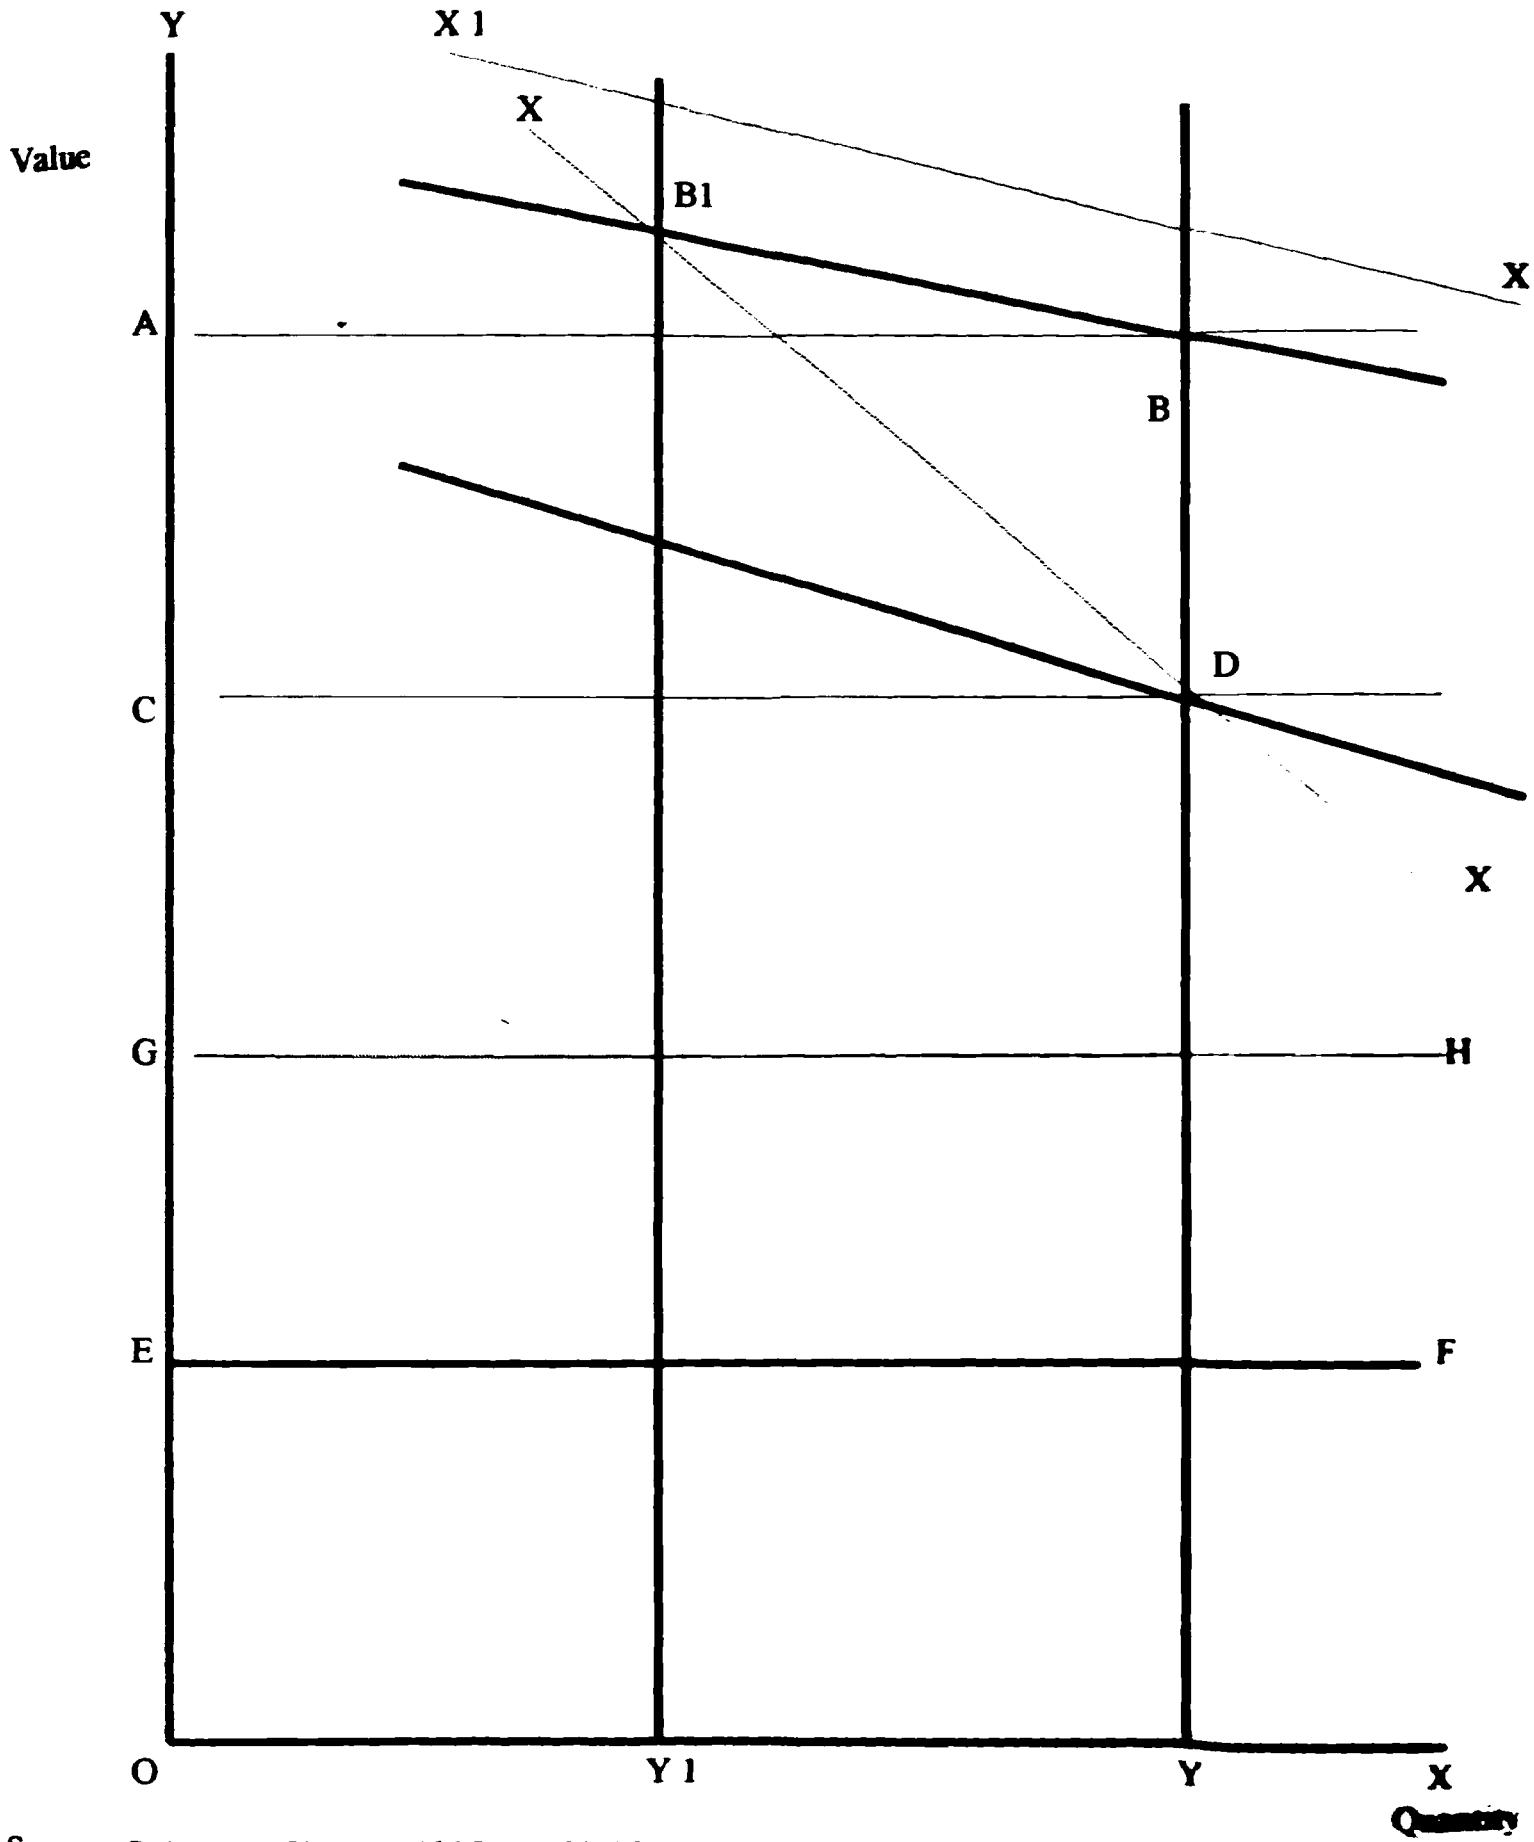
Subsidy is a payment made by the government or a private agency forming a wedge between the price paid by consumers and the costs incurred by producers such that the price is less than the marginal cost. Government subsidies alter the distribution of income in favour of particular class of income recipients. Although subsidies are often received by and paid by business, they ultimately affect the distribution of income among individuals. Subsidies are typically rationalised as means of achieving objectives other than or in addition to the redistribution of income that occurs. For example, subsidies to domestic producers are rationalised as means of promoting domestic employment. As another example, government may subsidise wage rates by paying a fraction of the employer's cost of living of a particular classes of labour. The wage rate paid by the employer does not increase with a wage subsidy as it does under a minimum wage law. Instead, it falls, and firms will be likely increase rather than reduce unemployment (Thomas F.Pogue and L.G.Sgontz, 1978, p.73). Subsidies are negative excise or sales taxes. The net effects would be the substitution effects of the subsidies; when an increase in expenditure is contemplated. For instance, the effect would be to cheapen goods relatively to leisure, and therefore, encourage more work in the subsidy case than in the transfer payment case, assuming substitutability between goods and leisure[1] (Prest Nabarr, 1985, pp.78-79).

Subsidies : Theory :

The concept of subsidy adopted actually the quantity of some service which is publicly provided. This publicly provided subsidy combines three different elements (see figure 7.0). OY be the quantity of some service which is publicly provided, YB the actual cost per unit, YD the efficient cost per unit and EF the curve of per unit recoveries. XX is the demand curve for the service. The rectangle ABHG measures the total volume of subsidy actually required in order to ensure that the market absorbs OY quantity of this publicly provided service if the market clearing quantity OY is considered socially inadequate. However, ABHG has two components, i.e, a necessary element CDHG which is a genuine allocative subsidy and an additional element ABDC paid to supplies to cover their inefficiency. Finally, there is a subsidy element GHFE which need not have been paid to support consumption level OY given the state of demand, this is a pure distributive subsidy. Thus, measure of subsidy which conceptually corresponds to the rectangle ABFE, combines a producers subsidy, the allocative subsidy and a distributive subsidy.

Such payments have a number of possible objectives. The first objective is a transfer from tax payers to producers or consumers of a particular good, i.e., a payment made to an individual (usually by a government body) which does not form part of any exchange of goods or services. Such transfer payment is part of the process of redistribution of an economy's output, for example, raising farmers' incomes. The second objective is to

FIGURE - 7.0



Source: Gulati and Sharma, 1995, pp. 93-95

influence the behaviour of producers or consumers via the mechanism of the elasticity of supply or demand, i.e., a measure of the percentage change in one variable in respect of a percentage change in another variable. The third objective is to keep the prices of certain goods low and stable. This occurs if price controls are holding down prices when general inflationary tendencies are present in the economy. For example, an anti-inflation policy (Pearce, W.David, 1986, P.406). Thus, while the subsidy can allow the government's total budget to be larger than the amount that it collected from the user fees, the amounts collected from the users must contribute, at the margin, to the size of the government's budget. This point may be clarified by the three examples, viz., fixed percentage of new investment costs subsidized by the government, subsidies based on a matching formula, and subsidies designed to meet budget shortfalls[2]. The purpose of deriving discount rates and conducting benefit-cost analysis is the efficient and socially desirable allocation of resources between private and government uses and within the government sector as well. The same ends require that user charges be imposed to confront the beneficiaries with the cost of selected goods and services provided by the government. This is desirable for three reasons : Firstly, it is equitable, secondly, the demand response to such levies provides an indication of the optimum amounts of facilities or services, and finally, if assessed so that the costs of furnishing additional capacity or services are borne by those who demand it, the charges at as a rationing device, limiting demand and encouraging use of economically more efficient alternatives. In other words, when govern-

ment is cast in the role of being a provider of private-type goods or services, its aim should be to duplicate a free-market mechanism, goods and services being produced only if consumers are willing to pay the full supply price. When this is not done, government programmes that support high-cost facilities tend to over expand, since there is no effective constraint on the demand for their services. This represents a misallocation of resources in that reallocation might yield a higher degree of social welfare (Gary Fromm and Paul Taubman, 1973, pp.46-47). Nonetheless, failing to adhere to a strict user benefit - charge relationship may be justifiable if by so ding greater over all public satisfactions can be provided to exist and to be realisable. For instance, when users are unwilling or unable to pay the supply price of the goods or services and large external effects can be reaped, the government may find it desirable to provide a subsidy equal to the difference between the supply and demand prices if this is less than the value of the external effects.

As said earlier, government subsidies may be defined as the difference between the cost of delivering various publicly provided goods or services and the recoveries arising from such deliveries (Small and Carruthers (1991), pp.143-44). However, a number of qualifications and adjustments must be introduced before this concept can be applied to measure subsidies. The subsidy concept is necessary in order to frame the interface between the government budget and public enterprises. So the difference between financial assistance extended to such enterprises and the returns which government revives from them is

included in, measure the volume of subsidies flowing through the government budget (Sudipto Mundle and Govinda Rao, 1991; P.1157). The wide range of general social and the economic services offered by the government at the centre and in the states can for analytical purposes, be classified in to three broad groups, VIZ., are public goods, private goods and merit goods (Musgrave, 1959, pp.42-43.) Public goods and services are characterized by non-rivalry and non-excludability, and no externality. A commodity or service which if supplied to one person can be made available to others at no extra cost. A public good is thus said to exhibit non-rival consumption - one person's consumption of the good does not reduce its availability to any one else. Non-excludability, that is if the good is provided the producer is unable to prevent anyone from consuming it. This characteristic prevents private markets from functioning since a seller would be unable to ensure that only those individuals who paid for the good could obtain it. Since the good could be obtained without payments no one would be willing to pay for it. Where consumption is non-rival, the charging of a price for the good or service is, in terms of the Pareto principle,[3] inefficient. This is so because adding an extra unit of consumption provides a benefit to the consumer without imposing any costs, while the charging of a price would prevent some consumption from taking place, thus causing a net loss of satisfaction or utility.

The provision of a public good is a matter of collective choice. Generally, public goods are provided by governments and paid for thoroughly compulsory taxation. An alternative solution

would be for all the members of a community to make a voluntary agreement to provide and pay for the good. The difficulty with this solution is that individuals may conceal their true valuation of the good in order to escape payment, (i.e., they may seek to be free riders). Private goods are characterized by rivalry, excludability and no externality. The first condition means that one person's consumption of the good reduces the quantity available to others. Excludability by the producer means that the producer can restrict use of the product to those consumers who are willing to pay for it. Exclusion by the consumer means that the consumer is not forced to consume the goods. Where goods display these characteristics, free exchange is possible and markets can operate.

Goods which are characterized by rivalry, excludability varying degrees of externalityes, are called merit goods. In the case of such goods, it is argued that consumer sovereignty does not hold and that if consumers are unwilling to purchase `adequate' quantities of such goods, they should be compelled or encouraged to do so. Of these, the concept of subsidy is properly applicable to only to the last two. In the case of pure public goods, from the theory of public expenditure pricing rules can not in fact be applied because of the free rider problem. For this, alternative method is that voting mechanism of near unanimity, choosing between alternative proposals along with associated tax prices, could lead to fairly efficient outcomes.

Public owned utilities have financial advantages which make it impossible to determine their relative economic merits by comprising their rate structure with privately owned utilities.

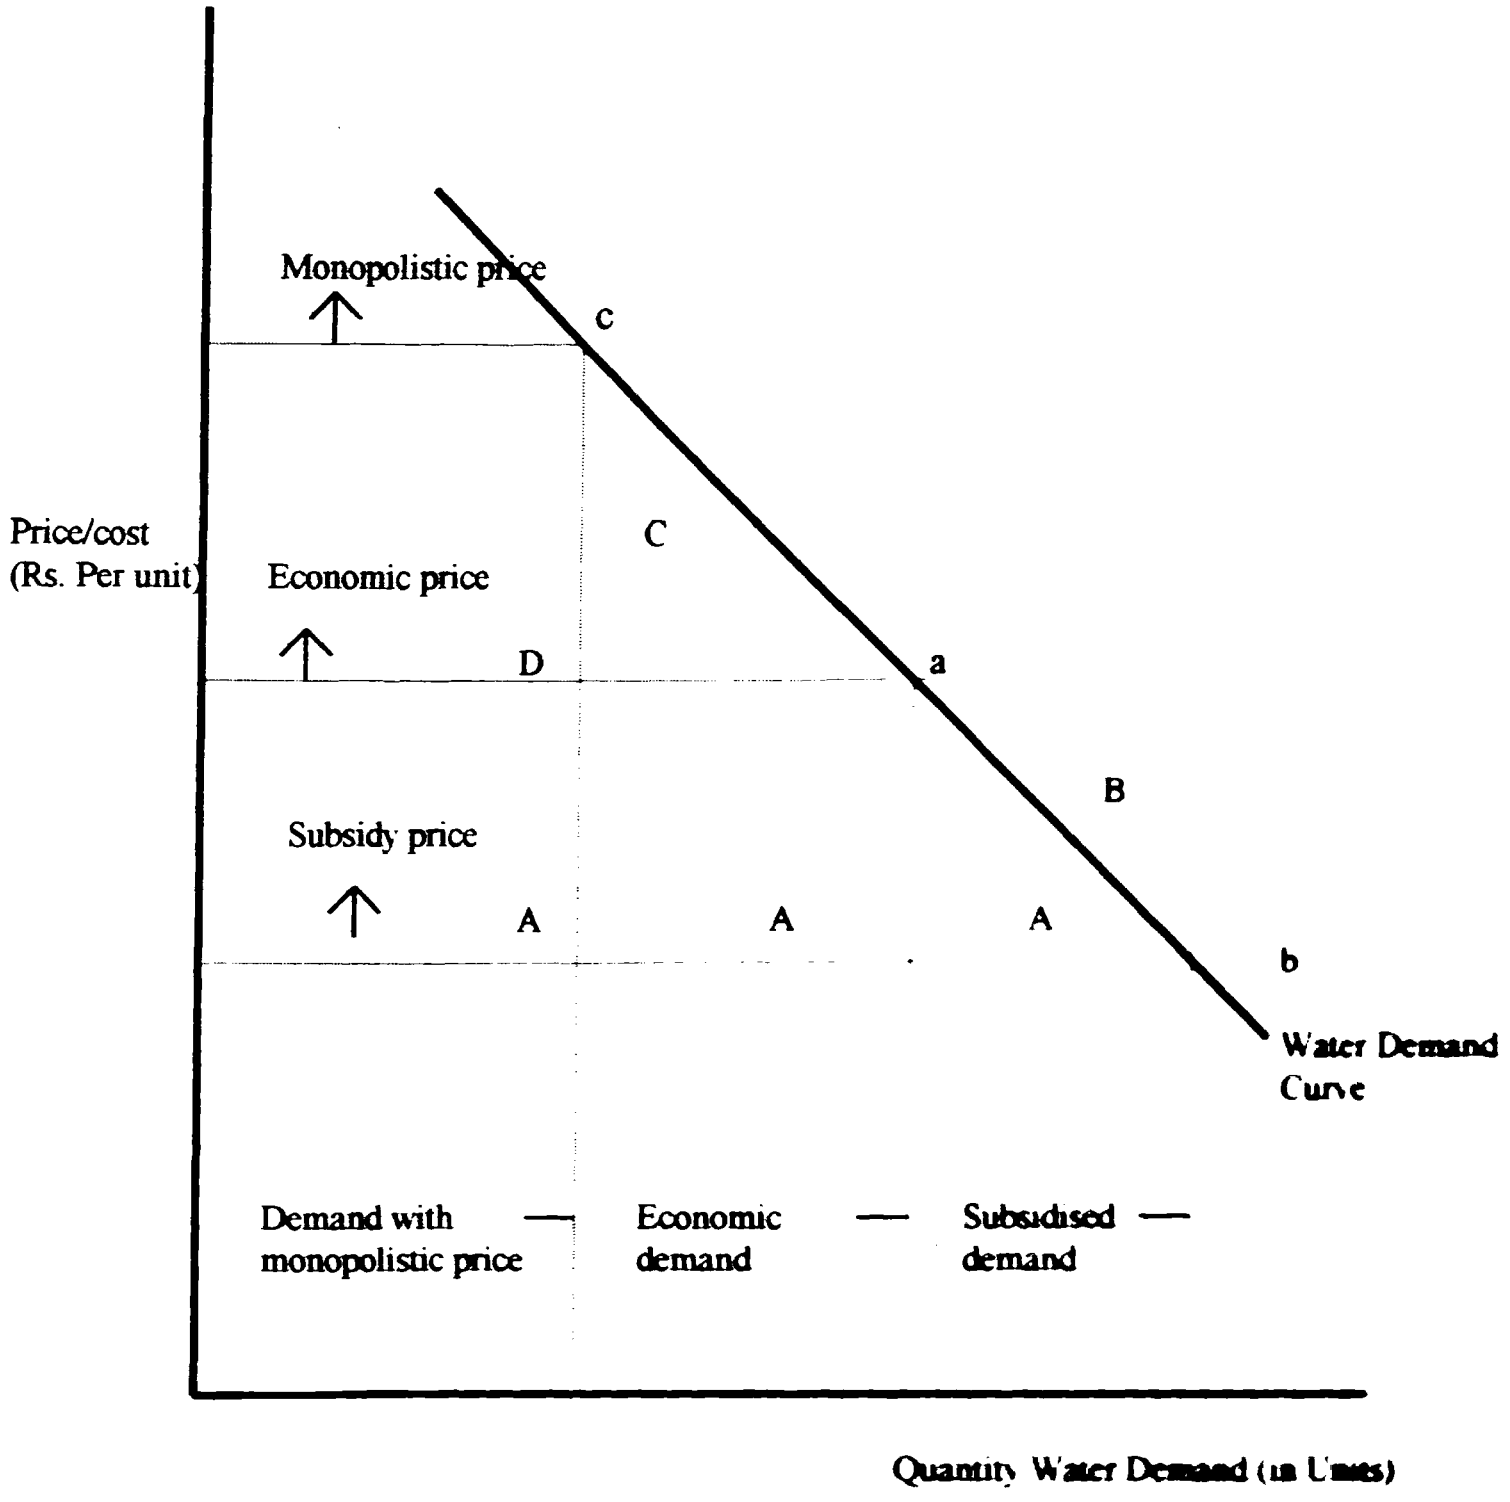
The lower financial burden allows public irrigation provided at the same economic cost to be sold for less than private irrigation provided.

As the difference between the project revenues and project cost must be recovered from other tax sources, low rates shift the financial burden from the irrigation user to the tax payer. "This suggests a net income transfer from other regions to the one in which the project is undertaken" (Krutilla and Eckstein, 1958, P.263). The magnitude of this income redistribution or subsidy is seen in Figure 7.1. At a fair market price, water use will be at a point "a". It subsidised public water lowers the price to point "b" area A represents the net income redistribution to consumers paid for any increased taxes. Area B also must be paid for by increased taxes and represents the cost of producing the additional water in excess of the value realised by the consumer. The low public water rates thus cause a net reduction in national income amounting to area B. It state regulation of public utilities does not overcome monopolistic pricing the net loss in national income will be represented by area "c". Thus, public preference clauses discourage economic efficiency by establishing criteria for sale other than the value of the water to the consumer.

FIGURE - 7.1

- If subsidy reduces price from a to b, A areas represent value of subsity to consumer, B area represents social cost of misallocation.

- If monopoly increases price from a to c, C area represents social cost of monopolistic misallocation, D area represents monopolistic profit.



Source: James L. Douglas and Robert R. Lee, 1971, p 349

In Pigouvian sense, "in a community in which wage rates are everywhere adjusted to the conditions of demand and supply, so that no wage-rates are un-economically high and there is no unemployment beyond what is necessary to allow adjustments to be made to industrial fluctuations, for the state to subsidise wages in particular industries must, in general, worsen the distribution of productive resources and damage the national dividend. A policy of wage subsidies applied to all industries would not necessarily damage the distribution of productive resources, but it could not improve this distribution; and though in some circumstances it might increase the dividend, it would probably only do so at the cost of causing too much work to be done, and therefore, in a manner injurious, and not beneficial, to economic welfare" (Pigou, A.C, 1962; P.699). Hence, subject to qualifications, in a community, in which, apart from subsidies, rates of wages would be every where adjusted to the conditions of demand and supply. So the policy of subsidy is likely not justifiable. Cases where, in publicly invested sectors like irrigation, subsidies are not as much healthier as possible.But in reality due to market distortions, subsidies play a key role in the distribution of national dividend. In an examplary note, the concept is analysed, as there are two factors of production : capital and labour. Labour is available in plenty at the prevailing wage rate. The stock of capital is given as an initial condition. It is a market economy. The employment-oriented planning under these circumstances can do two things. One is to reduce the wage rate, or the other is to increase the stock of capital over time.

A fall in wage rate would make the technique of production more labour intensive, and hence, a larger volume of labour would find job. On the other hand, an increase in the stock of capital goods would allow larger absorption of labour, even if the technical coefficient is fixed. The goal of full employment remains elusive for two practical reasons. The wage rate is already too low ; it can not be depressed any further. Besides, the stock of capital goods can not be adequately augmented because of the scarcity of consumer goods with which the workers to be engaged in proposed capital projects are fed. Now in literature two escape routes have been suggested. According to one study (Georgescu Roegen, 1960, pp.1-40), the rural economy is, it is argued, not capitalist, but feudal, in its mode of production, where wage paying employment is rare. Full employment can be attained in such a situation if a share cropping type of arrangement in distribution of income is agreed upon. According to the other study, the problem arising out of the scarcity of consumer goods for construction of capital goods can be circumvented if the relevant workers are persuaded to accept, in lieu of wage, a short of deferred payment in the form of partial ownership of the assets to be created by collective effort (Chakravarty. S, 1975, pp.1-11). Of the two proposed solutions, the first one is a non-starter so long as the wage rate is already at the level of subsistence. As for the second one, it calls for a fundamental change in the concept and practice of ownership right to property.

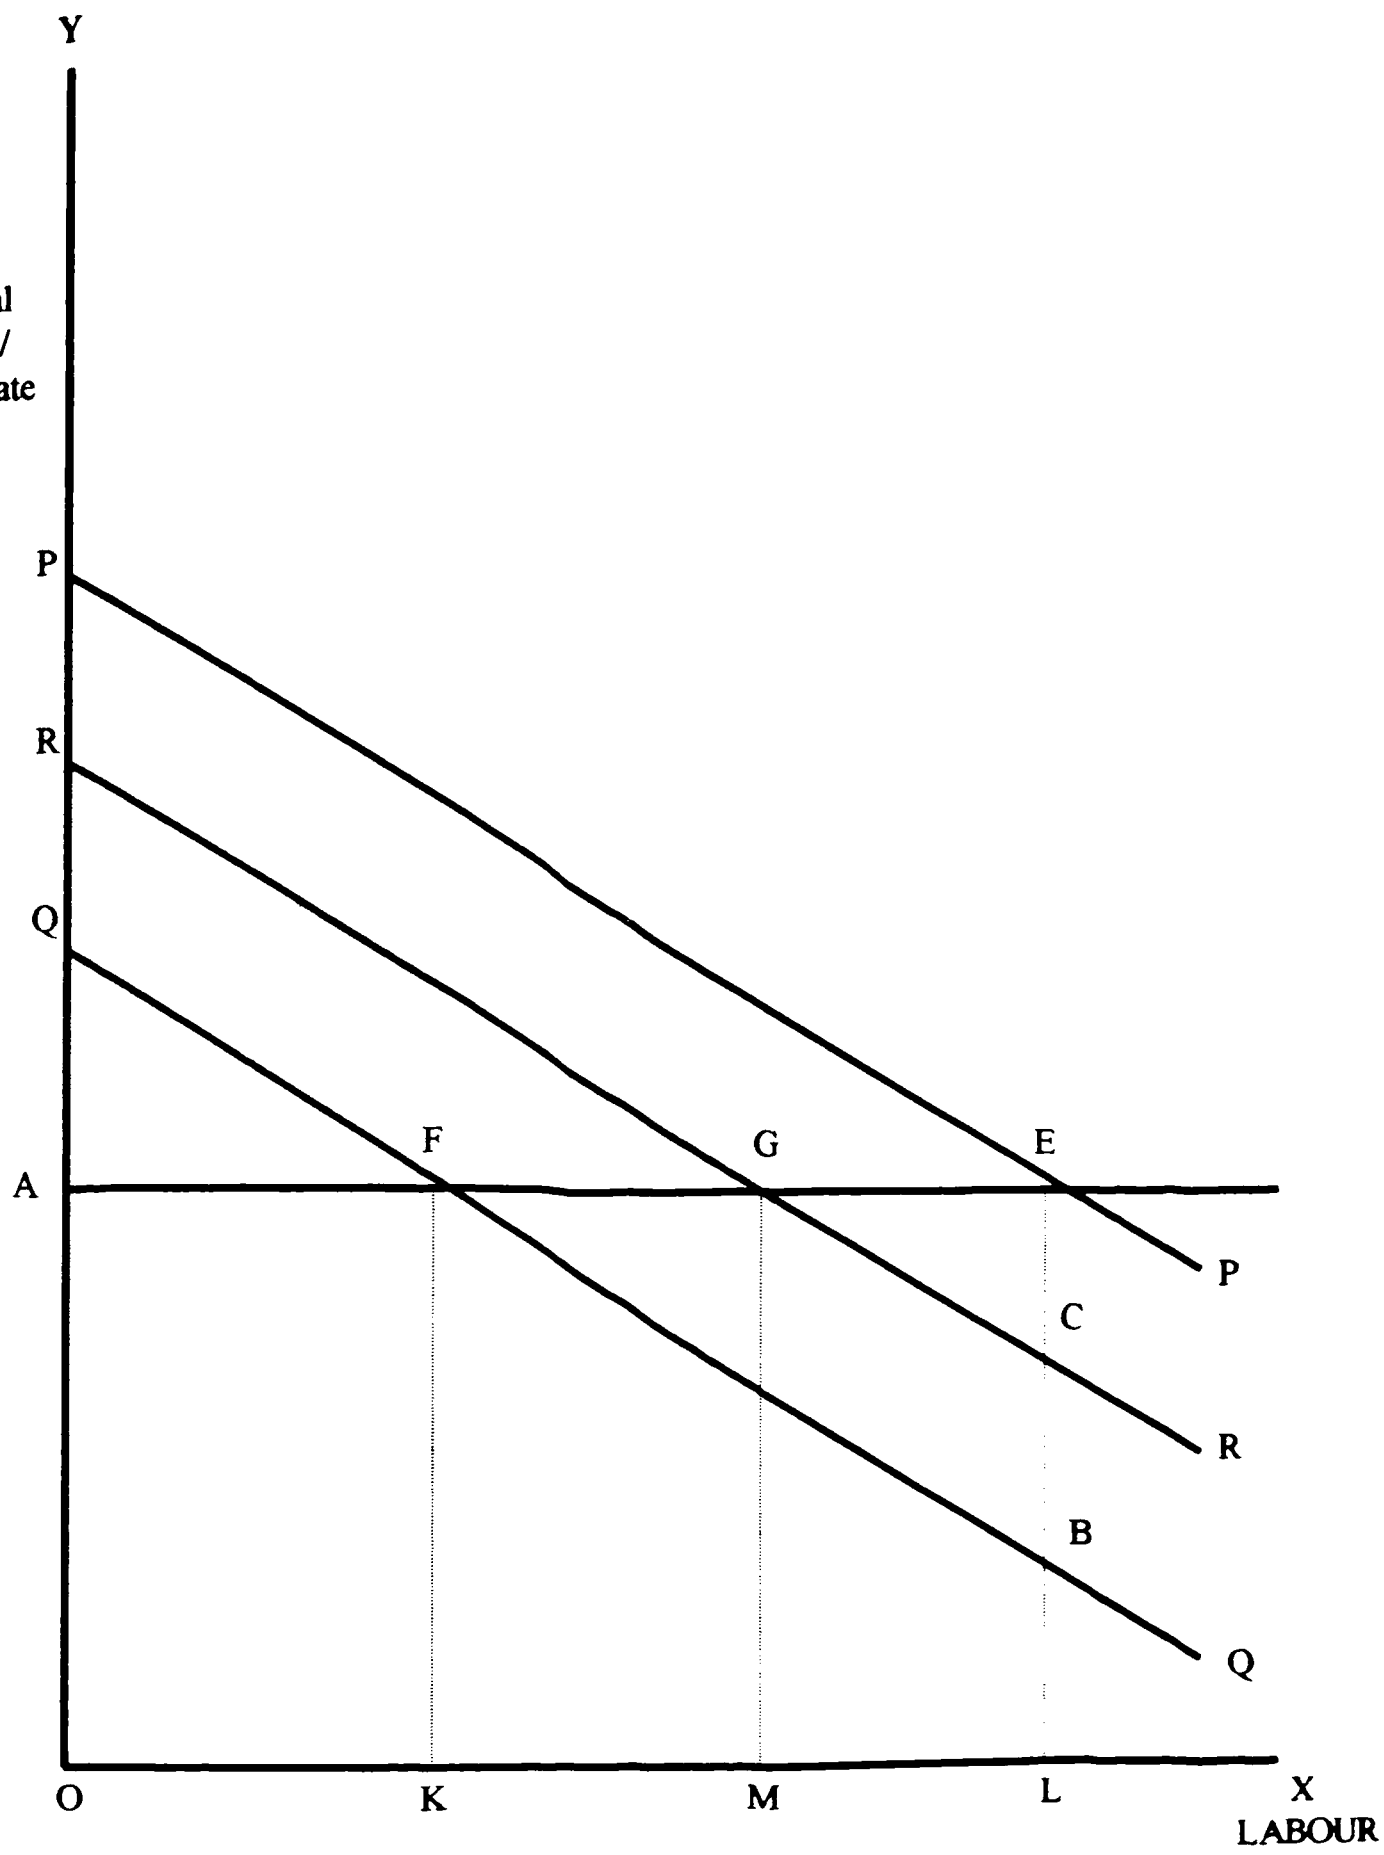
WAGE SUBSIDY:

Consider a simple situation as follows (see figure 7.2). In the figure 6.1 the amount of cultivated land is given. It can be cropped twice. PP is the curve of marginal productivity of labour engaged during the first crop. The curve slopes down, for land is heterogeneous ; land is cultivated in a descending order of fertility. Labour coefficient per unit of land is fixed. OL is the total supply of labour, which is homogeneous, available at wage rate OA. The initial equilibrium is at E where there is full employment of labour and land. In short, the agricultural sector has full employment during the season of the first crop. QQ is the marginal productivity of labour during the second crop. The wage rate being OA, the employment in this season is OK, and the corresponding cropping intensity is OK/OL. Unemployment in this season is measured by KL, and the problem is essentially to get rid of it by increasing the intensity of cropping.

Once straight forward way of doing so is to give wage subsidy to the farmers, to the tune of FEB, which is the deficit they would incur if they employ the additional volume of labour KL. The exact mechanism of administering the subsidy so as to ensure the corresponding employment is a separate matter.

Another way of resolving the unemployment problem could be as follows. It involves two steps. One step is to employ all or part of KL to construct some capital goods, irrigation channels, wells, organic fertilizers, etc. With those assets in hand, then, the marginal productivity curve QQ shifts up to RR. The

FIGURE - 7.2



Source: Ranjit Sau, 1996, pp. 385-386.

other step is that, in a market economy, accordingly, employment during the second crop season would tend to be OM; but it can be stretched to OL if a wage subsidy by the amount of GEC is given to the farmers.

Here there are two alternative ways of having full employment in the agricultural sector. Under the first alternative the output was OQBL, as against ORCL in the other. One can choose that combination of subsidies and output which minimizes the average subsidy per unit of output, subject to full employment. It would involve a particular amount of subsidy to construct durable assets with rural labour, and a particular amount of subsidy to cultivate the land for raising a second crop. Any deviation from this mix would create an imbalance. But areas where the presence of excess capacity (such as irrigation) the amount of subsidy should be narrowed due to fiscal imbalances.

Subsidies play a crucial role in stimulating development of any country through increased agricultural production, employment and investment. They are advanced either to promote the use of new inputs or to transfer income in favour of farming community. (Gulati and Sharma, 1995, P. A-94). Governments may pay much higher prices for the agricultural products than what the farmers can obtain under free market environment, and by supplying these especially in case of non-tradable inputs of below the price that would prevail in an open free trade environment (as in case of tradable inputs). Higher prices for farm products can be provided mainly by insulating the domestic markets from the world

economy through a restrictive trade policy. On the other hand, vital inputs like fertilizers, irrigation water, credit electricity used in the agricultural sector can be supplied to the farmers at prices which one below them would be open market prices. The prices of these inputs, therefore, do not reflect their true value, i.e., the real cost of supplying these inputs.

These are some reasons for which subsidies on inputs are normally preferred. Benefits of government expenditure can be derived by the farmers only in proportion to their use of inputs (Gulati and Sharma, 1995, P.A-94). Input subsidization also avoids rising food and raw material prices, thus avoiding the plausible adverse effect on growing industrial sector or large mass of poor living in the developing countries.

Cost of input subsidies have to be evaluated against the loss of potential benefit if the same amount was invested in creating productive potential of agriculture. It is argued that incentives like subsidies are short term measures and they are not meant to be substitutes for the long-term measures in social and physical infrastructures, which alone ensure the viability of the new technology. Even in the short-term a sharp rise in subsidies may cut into the resources available for productive investments and this is what seems to have happened in the Indian context (Gulati and Sharma; 1995, P. 95). Input subsidies are cutting into the resources which could have been invested in generating new productive potentials. This is because in a country like India where resources are limited, the achievement of

any particular objective usually comes at the expense of other competing objective, a major chunk of the increase in resource flowing is being diverted to meet the expenditures originating from high input subsidies rather than making investment in agriculture. The recovery ratio is less when compared to expenditures incurred to particular sector.

Subsidies on irrigation are generally viewed on the assumption that these are temporary measures and would be withdrawn once the objectives are achieved. But past experience clearly shows that it becomes increasingly difficult to reduce or abandon subsidies. In fact, there is nothing wrong with subsidies if they are well targeted and reach the intended beneficiaries and have a definite time frame for their termination. But subsidies share has been appropriated by fewer well developed regions and better off sections of the farming community. In well-developed command areas, the well off sections with large size of operational holdings, are much more beneficiaries than those having small size of operational holders. And also these subsidies distort the choice of commodities and choice of techniques for each commodity lead to inefficient cropping pattern.

Considering the fact that there are implicit and explicit input subsidies in Indian agriculture. This could be worked out from the farmer's point of view, from the view point of the input supplying agencies and from the societies point view (Gulati, et.al.,, 1995, p.A-95). From the view point of the farmer who is a user of inputs the subsidy could be defined as the difference

between what he is willing to pay for it and what he is actually paying. In this case the maximum that a farmer would be willing to pay would be equal to the marginal value product of input use. From the view pint of input supplying agencies, the subsidy could be defined as the difference between the cost of supplying these inputs and revenue received from the farmers. And from the societies view point subsidy could be defined as the difference between true resource cost of supplying inputs measured at shadow prices and what the farmers pay for it. An attempt have been made in this context from the view point of suppliers of inputs subsidy such as irrigation, electricity and fertilizer who help to get supplies of these inputs (see Appendix-VII-i). Thus, subsidy may be defined as the difference between the cost of supplying a particular input and the recoveries from supplies.

While agriculture sector has prospered in many states and has created a large class of prosperous farmers, there is hardly any attempt at raising resources through direct taxation, but receive significant subsidies (Sukhamoy Chakravarty, 1988, P.77). The situation where, the balance from current revenues at 1984-85 rates of taxes for the VII Plan is placed at Rs.52.490 million (VI Plan Rs.18,930 million). India's budget is concerned the balance from current revenues works out at Rs.1,20,110 million for the same period. This is explained by large increases under three headings, viz., subsidies, interest payments and defence. Budgetary loss on account of operation of government irrigation systems were estimated (see Appendix-VII-ii). Based on data available in National Accounts Statistics. The implicit subsidy

per hectare of canal irrigated area had been increased tremendously (eight fold) during the period 1950-51 to 1982-83.

SUBSIDIES : A CROSS COUNTRY VIEW :

The subsidy issue in the world front has risen especially under the Uruguay Round of GATT negotiations. Mostly, the distortions in world trade of agricultural commodities that have arisen because of direct and indirect subsidies provided by several governments to this sector. The distortions are reflected in the `unreal' level and behaviour of world prices of agricultural commodities. These are often transmitted to production baskets of different countries, as they produce commodities against the logic of comparative advantage. It leads to huge efficiency losses. All major country groups were responsible for the subsidies/distortions present in the world today. The U.S. requested that agriculture should not be included in the GATT. The common agriculture policy formulated by the EC, which created surpluses that were dumped in the world markets, was the main factor. The developing countries had little say in world policy matters.

There may be different ways of subsidizing cultivators through government intervention. The way of subsidies is that a set of domestic and external policies that allow domestic cultivators to receive much higher prices for their outputs than would have been possible under a free-trade scenario. This set would include domestic support price policies, tariffs, quotas, export enhancement programmes, price stabilization measures and import

licensing as well as canalizing of policies related to external trade. If these policies push domestic price higher than the corresponding border reference prices, then the cultivators are `protected' or implicitly `subsidized'. On the contrary, if domestic prices are lower than they would be under a free-trade scenario, cultivators are deemed to be `disprotected' or `taxed'. The second way of subsidies to cultivators is by providing them input prices below their cost of supply (import-export parity price in case of tradables, cost of production in case of non-tradables), or at prices that are lower than that being charged from other consumers of the same product (particularly in case of non-tradables) (Gulati and Sharma, 1992, pp.106-109). Examples would be subsidies in electricity, credit, fertilizers, transport and irrigation. The third way would be to provide direct payments to cultivators to produce through deficiency, diversion and disaster payments and marketing loans. World agriculture is subsidized to the tune of 18% of its value. With range of percentage producers' subsidy equivalent stretches from 54.5% in Columbia to 72.5% in Japan, with a weighted average for the countries covered at 18.4%.

TABLE - 7.1 DEGREE OF STATE SUPPORT MAJOR COUNTRY GROUPS(AVERAGE FOR 1982-87)

COUNTRY	PRODUCERS' SUBSIDY EQUIVALENTS (%)	SHARE IN VALUE PRODUCTION (%)
1. United States	26.17	18.74
2. Japan	72.50	6.43
3. EC-10	37.00	19.08
4. Cairns group	14.11	8.40
5. Developing group	26.91	24.02
6. Less developed group	-25.04	23.34
All	18.4	100.00
Total value of production (in $ billions)		532

Source : Data given by Gulati and Sharma, 1992, pp.1-109.

At the macro level, Japan emerged as the highest protector of its farm sector, followed by the European Community, the US and finally the developing group (see Table 7.1). The less developed group of countries appeared to tax its producers but not consumers. India will be one of the gainers from the lowering of protection levels in world agriculture.

TRENDS IN SUBSIDIES IN INDIA:

The trends show the actual volume of subsidies was large, amounting to Rs 42,324 crores or almost 15% of the G.D.P[4] in 1987-88. Subsidies in economic services amounted to Rs.25,564 crore or about 60% of the total volume of subsidies. A little

over half of this flowed through the central budget. Costs were not fully recovered in any economic service and the average recovery rate was less than 44%. The cost of these services, taken along with irrigation and flood control was close to Rs.15,000 crore. Only about 20% of this cost was recovered, leaving a subsidy element to around Rs.11,554 crore (Government of India, 1992, pp.47-50). The un-covered costs of economic services such as irrigation, power, agriculture and transport have risen faster than those of social services, such as education, health, water supply, sanitation and roads the difference being more pronounced in the states. At the state level the un recovered costs have consistently exceeded plan outlays during the last two decades. But the ratio widened dramatically from 1.28 in 1977-78 to 1.75 in 1987-88.

Two alternative estimates[5] of the unrecovered costs of providing irrigation service from major and medium works in 2 years namely 1977-78 and 1986-87, based entirely on the Central Water Commission's compilation, except for adding depreciation at the rate of 1% and using the figures of gross receipts and working expenses from the same source, but taking the capital base with a three year lag interest at the average borrowing cost and depreciation at 1%.

TABLE 7.2 ESTIMATES OF UNRECOVERED COSTS ON ACCOUNT OF MAJOR AND MEDIUM AND MULTIPURPOSE IRRIGATION PROJECTS OF 14 MAJOR STATES OF THE INDIAN UNION.

(RS. IN MILLIONS)

ITEM	C.W.C		1992 REPORT	
	1977-98	1986-87	1977-78	1986-87
Gross receipts	969	1667	969	1667
Working expenses	1272	4927	1272	4927
Interest on capital (average borrowing of cost)	2155	8506	2113	10589
Depreciation @ 1%	600	2023	385	1406
	4027	15456	3770	16922
Un recovered costs	3058	13789	2801	15255

Source : **Government of India** ; 1992, pp.48-50).

On the basis of the estimate of 1992 Report of the total unrecovered costs account of major and medium irrigation works increased more than five fold in a 10 year period from Rs.2800 million in 1977-78 to Rs.15250 million in 1986-87 (see Table 7.2). If so much of the country's resources were not spent on these recurrent subsidies, productive investment including investments in irrigation could have been stepped up to achieve and sustain income and employment.

Unrecovered costs are essentially subsidies but one must not assume that the entire subsidy accrues to users of irrigation. Part of it represents the costs of inefficiency in producing and

distributing irrigation services on account of defective design, inordinate delays in completing projects, over-extended distributary systems, waste, and other factors which inflate capital costs; and over-manning, relatively high administrative costs, avoidably high costs repair works and other factor which raise operation costs, and affect the efficiency of assessment and collection of revenue (Vaidhyanathan, 1992; pp.49-53). It is not possible to determine how much of the implicit subsidy is attributable to inefficiency and how much really benefits farmers because of the under-pricing of water.

STATE-WISE SUBSIDY IN IRRIGATION :

State-wise irrigation subsidy[6] per hectare of gross irrigated area (through major and medium irrigation) consists of the annualized capital cost at 10% of capital outlay invested per hectare of gross irrigated area (8.44% as interest cost and the rest as depreciation charges) plus operation and maintenance expenses incurred on these schemes (per hectare of gross Irrigated area (GIA), and minus gross receipts from the schemes on per hectare GIA basis (Gulati, A; 1989; P A-59). Multiplying these resulting estimates by gross irrigated area under major and medium irrigation projects, obtains subsidies.

TABLE. 7.3 TOTAL IRRIGATION SUBSIDY FROM MAJOR AND MEDIUM IRRIGATION SCHEMES OF MAJOR STATES FROM 1980-81 TO 1986-87

STATES	YEAR							TOTAL AVERAGE 80-81 TO 86-87
	80-81	81-82	82-83	83-84	84-85	85-86	86-87

Source : Data based on, Gulati; A; 1989, pp. A-57-60.

It may be noted that during the eighties' (1980-81 to 1986-87) on an average at all India level, irrigation subsidy amounted to Rs.6500 crore per annum (see Table 7.3). Uttar Pradesh accounted for more than Rs.1000 crore, along with states Andhra Pradesh Rs.662.50, Bihar Rs.540.74, Rajasthan Rs.483.46) and Punjab Rs.471.63. Their share came to almost one half of all India irrigation subsidy.

TRENDS IN SUBSIDIES : ANDHRA PRADESH :

The expenditure of the Andhra Pradesh Government on subsidies increased from Rs.122.87 crore in 1981-82 to Rs.478.03 crore in 1986-87, registering a compound growth rate of 31.2% (see Table 7.4). Agriculture occupies an important place as a receiver of subsidies. However, there is a decline in its share from 95% in 1981-82 to 60% in 1986-87. This decline is due to the decrease in the share of irrigation and electricity subsidies. The share of irrigation subsidy declined from 75% in 1981-82 to 48% in 1986-87 (see Table 6.3). The extent of subsidy given by the irrigation department to the agriculture sector is computed as, the rate of return on the invested capital and working expenses are added, and from gross receipts, the total costs are deducted in order to compute net profits (losses). If the department incurs losses, the losses are treated as the extent of subsidy given to the agriculture sector (see Table 6.3). The implicitly means that capital cost of major and medium irrigation schemes should be treated as sunk and goes in the form of subsidy.

TABLE. 7.4.FINANCIAL RESULTS OF MAJOR AND MEDIUM IRRIGATION WORKS IN ANDHRA PRADESH

(RS. IN CRORES)

ITEM	YEAR		
	1976-77	1977-78	1978-79
Capital outlay to end of the year	222.19	253.51	278.79
Total revenue during the year	10.92	9.92	10.78
Working expenses during the year	9.85	9.30	8.11
Net surplus before meeting interest	+ 1.07	+ 0.62	2.67
Interest on Capital	7.70	9.76	11.07
Deficit after meeting interest	- 6.63	- 9.14	- 8.40

It was further depreciated at the rate of 1% on mean capital outlay in 1987-88 to 1989-90 (see Table 7.5).

TABLE. 7.5 **FINANCIAL RESULTS OF MAJOR AND MEDIUM IRRIGATION 'PROJECTS IN ANDHRA PRADESH**

(RS. IN CRORES)

ITEM	YEAR		
	1987-88	1988-89	1989-90
Capital outlay to end of the year	2335.42	2625.16	2898.37
Total receipts during the year	54.37	54.41	35.21
Revenue expenditure during the end of the year	134.64	490.98	315.54
Depreciation	23.35	24.80	27.62
Expenditure (excluding depreciation) over receipts	129.20	485.54	280.33
Expenditure (including depreciation) over receipts	152.55	510.35	30.7.95

Source : **Reports of Eighth and Ninth Finance Commission 1984-85 to 1989-90 and 1989-90 to 1990-95, Dec. 1989, Annexure III-10.**

The recent white paper (1996), published by the Andhra Pradesh Government gives a dimensional perceptive to the issue by indicating the relative magnitudes of direct and hidden subsidies (Subba Rao and Madhava Rao, 1996, P.4). The high profile Rs.2% per kg rice scheme by far the largest food subsidy programme by any state government, accounts for over Rs.1300 crore. Even this is largely estimated at Rs.4366 crore based on current costs. The water rate charged at Rs.60 per acre, as opposed to the average cost of delivery of water of Rs.8150 per acre, does not cover even the operative and maintenance expenditure, let alone yielding a return on the huge investment made. These subsidies in irrigation sector might decrease the national dividend, mounting the fiscal deficit and misuses the input.

The impact of subsidy in irrigation based agricultural growth has diverted bulk of input subsidy to irrigated areas with serious implications not only for inter-crop parity but also inter-class and inter-region and equity, (i.e., irrigated versus un-irrigated farmers and irrigated versus dry land regions (Subba Rao, 1985; PP.523-46). It has been found that most of the share of input subsidies has been appropriated by fewer well-watered and well developed regions.

Ansari discussed theoretically that "the application of principle of equating prices with marginal cost with a view to maximizing social welfare which when applied to a decreasing cost industry like irrigation would yield deficit" (Ansari, N. 1968, P.8). All these works reveal that subsidy in irrigation sector

hinders the further expansion of irrigation development. While substantial price increases of most publicly provided goods and services are necessary, the adjustment has to be gradual. In the case of surface irrigation, it is a five-fold rate increase is needed even to recover the current operation and maintenance costs and a small part of the capital charges.

Conclusion:

Public owned utilities have financial advantages which make it impossible to determine their relative structure with privately owned utilities. The lower financial burden allows public irrigation provided at the same economic cost to be sold for less than private irrigation provided. As the difference between the project revenues and project cost must be recovered from other tax sources, low rates shift the financial burden from the irrigation user to the tax payer.

Subsidies affected the development of irrigation in two ways: inefficient maintenance of the irrigation works and discouraged the new investment. A sharp rise in subsidies may cut into the resources available for productive investments. This is what seems to have happened in the Indian context. Budgetary loss on account of operation of government irrigation systems were estimated that per hectare of canal irrigated area has been increased eight fold. If so much of the country's resources were not spent on these recurrent subsidies, production investment including investments in irrigation could have been stepped up to achieve and sustain income and employment.

1. **Estimation of Input subsidies** : Gulati, et.al (1995) "Subsidy Syndrome in Indian Agriculture", E.P.W, Vol.XXX, No.39, September 30, pp.A-95-A-97.

(i) **Irrigation subsidy**: It can be estimated under two alternative definitions (see below Table).

a) **Estimate - I** - As the difference between Operation and Maintenance expenses and the recoveries from farmers. This means that irrigation works are subsidised to the extent of the difference between gross receipts and the operation and maintenance expenses incurred by project authorities.

b) **Estimate - II** - Subsidy on working Expenses and Capital Outlay: because money invested in various irrigation schemes has its opportunity cost which must be considered along with operation and maintenance costs. One way to determine the opportunity cost of this investment would be look at the annualised yield of capital. This calls for finding out an appropriate rate of interest, and also a rate of depreciation for major and medium and minor irrigation schemes. Thus, the rate of interest (average redemption yield of government securities) was taken as 8.5% which is an average redemption yield on government bonds as well as approximate cost of borrowing funds by the government. And, the rate of depreciation were taken as 1.5% in case of major and medium irrigation schemes and 4% in case of minor irrigation to

estimate the annualised cost of capital employed in irrigation works.

ii) **Electricity Subsidy** : Subsidy on electricity could be determined in two different ways. One way out is to work out the difference between the tariff charged from the agricultural sector and the shadow price of the electricity which goes towards irrigation purposes. The second method could be to find the opportunity cost of resources which are used in the generation and distribution of electricity. the alternative adopted here to estimate subsidy, however, is by taking the difference between the average cost of supplying electricity to various sectors and the tariff charged from agricultural sector and multiply this difference with the quantum of electricity used in agriculture.

iii) **Fertilizer Subsidy** : Fertilizer subsidy could be estimated under the assumption that if government had not intervened in (the system either through retention price scheme (RPS) or through controls on the imports of fertilizers, at what price farmers would have got fertilizers. The difference between what cultivators would have paid under that counter-factual free-trade scenario and what they are actually paying may be termed as "economic" subsidy to farmers. The economic subsidy on fertilizers per unit of urea (46%. N), di-ammonium phosphate (DAP) (18-46-0) and muriate of potash (60% to 20) has been worked out. These estimates are adjusted to derive separately economic subsidy per ton of N, P and K, and then multiplied by the respective quantities of their consumption to obtain total economic subsidy on fertilizers.

INPUT SUBSIDIES IN INDIAN AGRICULTURE

NOTES:

1. More generally, if revenue is raised in a given form - say, proportional income tax, for simplicity - the combined effects o revenue raising and disbursement on work incentives will depend on th constituents of government expenditure. As a first approximation income effects will cancel out and so the net effect will depend o substitution effects. When expenditure side substitution effects ar important (e.g. if the revenue is used to subsidise wage goods and s increase the attractiveness of work at the margin) the disincentiv effect will be less than where they are not (e.g. transfer paymen which are made irrespective of work effect) (Prest Nabarr, 1985 P.79).

2. Instead of correcting such trends like overdependence on debts laxity in collection of revenues, improper collection of non-ta revenues, leaving untouched several resources which could have bee tapped and so on, the guns were turned on subsidies as the main reaso for budget deficits. When subsidies are given to influential section of society, cutting such subsidies is next to impossible. In contras subsidies to poor are mercilessly cut. For instance, the governmen succumbed to rich farmers' pressures and gave up installation o metres to measure power consumption, while subsidised rice pric increased (V.Hanumantha Rao, 1998, P.407).

3. When the economy's resources and output are allocated in such way that no reallocation can make anyone better off without making a least one other person worse off then a Pareto optimum is said t

exist (Pearce, W.David, 1986, P.320.

4. A measure of the money value of the goods and services becomin available to the nation from economic activity Pearced, W.David, 1986 p.175).

5. The Report of the Committee on pricing of irrigation water (1992 takes the data of unrecovered costs made by the National Institute o Public finance and Policy (NIPFP) based on an independent tabulatio of figures from the budget documents of State Governments for tw years, namely 1997-98 and 1987-88. The NIPFP tabulation covers no only major and medium irrigation projects but also figures relating t minor irrigation and Command Area Development. To this extent, it coverage is widen than that of the CWC's compilation. However , th NIPFP figures on gross receipts and working expenses relating to majo and medium irrigation projects are substantially at variance fro those in the CWC compilation, though both draw upon the same source Moreover, NIPFP tends to understate the unrecovered cost because i takes credit for the interest receipt figuring under the head `inter est' in the accounts, which is the result merely of a book adjustmen and does not represent a genuine interest amount received from th beneficiaries. They also take into account the loans given by th government to tube well corporations, farmers, etc. The pricing o Irrigation Committee (1992) feel that direct government expenditur and loans to others should be kept distinct. However, the pricing o Irrigation Committee (1992) followed NIPFP in including depreciatio in 1992 committee calculations and adopting the average borrowing cos rather than the interest rate used in the accounts. As regards th

capital-base, the 1992 committee adopted a 3 year lag instead of one-year lag as in the NIPFP tables (Government of India, 1992 P.49).

6. The Committee on pricing of Irrigation Water (1992), presente the data on unrecovered costs for more recent years from the account of State Governments. there are problem of comparability betwee these figures and the figures relating to earlier years because ther was a change in the classification scheme in 1987-88. Moreover, th interest calculations in the later years are based on the rates adopt ed by the State Governments which vary widely from State to State an are significantly different from the average borrowing cost which th committee (1992) adopted in their own calculations.

7. It has been realised that recovery rates should cover workin expenses and a part of capital outlay. Rough estimates indicate tha raising the price of water to the extent needed to just cover th Operation and Maintenance expenses and above 1% of the capital cost workout only 6% of the gross value of output per hectare of output pe irrigated hectare. Thus, the present fiscal imbalances may caus further expansion of allocative budget difficult owing to these subsi dies (GOI, 1992, pp.48-50).

CHAPTER-VIII

CONCLUSION

This chapter is divided into three sections. The first section summarises the chapters of the thesis. The second section compares and contrasts the present work with other works, while the final section gives the essence of the thesis.

SECTION - I

Efficient management of water resources requires the recognition of the fact that the overall water resources should be linked to the national economy. A country's overall development strategy, use of macro-economic and trade policies and fiscal policy, government expenditure on irrigation, flood control and building of dams affect the demand and investment in water-related activities both directly and indirectly.

There is a limitation in reconciling water as a purely economic good with the traditional idea of water as a basic necessity for humanity. Water was once considered as free good, but now it is becoming scarce. Scarcity is one of the most important issues in considering the various socio-economic trade-offs in allocating water among different uses. Developing effective water use policies is difficult for a number of reasons. They are mainly the physical and administrative issues. Water is used in several productive activities. These are eco-

nomic benefits from commodities, waste assimilation, aesthetic and recreational, fish and wild life habitats. Along these benefits, many pressing irrigation issues reflect the various economic, social and political influences affecting economic conditions.

To achieve these objectives, many countries rely on a mix of market policies and direct government interventions now and then to manage water resources. A competitive market system has certain desirable properties. One is that the system would produce the maximum valued bundles of goods and services to consumers. The second property is its ability to accommodate change in the conditions of production and pattern of consumption. The actual market system may not always meet the precise pre-conditions of the competition. The principal problems arise with public or collective goods which are non-rival in consumption, external or spill over costs and un-compensated side effects. competitive markets in water are not yet common any where in the world as means to a more productive use of resources. General reasons are; physical-due to hydrological cycle, it is relatively difficult to identify specific limits of water and productive, consumption uses. Economic reasons once water was plentiful supply, now it become a scarcity one and conflicting social values- these reasons may arise due to allocation water among different uses. Private good uses rival in consumption and neglect the physical, economic and conflicting social values. Government intervention in water related markets, it is easy access and regulating the resource. Government intervention also

deals the many issues like economic, social and political influences. Unfortunately, providing subsidies and repeated under-investments Government intervention facing financial crunch when dealing with water-related activities. The overall performance of many irrigation projects is disappointing. It including cost over-runs, poor management, and nonrealisation of full cost recovery. It leads to the discussion of the economics pricing of the irrigation water.

The level of irrigation charges is justified on economic grounds, only if price equals marginal cost; then only market forces ensure the economic level production. The financial and economic functions of water charges are satisfied simultaneously under pure competition. The market reaches an equilibrium point where the long-run marginal cost equals the marginal benefit to fix the price and the output. Because of this intersection, marginal cost equals average cost, the product of price and output equals the total cost and the financial requirement is satisfied. Because the marginal cost equals the price, the economic requirement is also satisfied. Under the conditions of increasing/decreasing average cost, there is a conflict between financial and economic requirement. To achieve these objectives three alternative approaches are available for reconciling economic and financial requirements. First is the price discrimination, but it may lead economic inefficiency. The second is the distortion in resource allocation by diverting the tax funds. The third is maintaining the marginal cost pricing is to levy a non-marginal charge or tax on those using the output.

Pricing policies are generally motivated by national objectives of achieving economic efficiency and income distribution. If the goal of a pricing policy is economic efficiency, then economic principles must apply. In a strictly economic sense, a water user can afford an irrigation fee as long as that fee is smaller than his or her additional net income that is attributable to irrigation. If the goal is to redistribute income to particular groups, then the principle of subsidised pricing is used. The economic efficiency goal is generally pursued where that water should be treated as an economic good.

Considering the principles of water rate fixation, cost of service is the traditional method of pricing of utilities including water utilities. In each system, price is related to the cost of providing the specific service. It includes the cost of capital, administration and operation and maintenance. Costs properly charged to water production. Pricing on the basis of ability to pay is a method for society to redistribute income. Prices are set at less than the cost of supply for a class of users or a purpose or use. The opportunity cost is a method of pricing. The charges for water are set to recover the true cost of the investment, which is the value to society that could be achieved if the same investment were made else where or benefits realised from alternative opportunities that must be forgone. The other method of pricing of water is the marginal or incremental pricing sets the rates equal to the cost of producing the last unit of water supply. This method places the burden of in-

creased demands on those that cause the increase. Finally, the net benefit principle seeks that the rate should form some fixed potion of the difference between the additional yield resulting from the irrigation and the additional expenditure incurred in the process. There is a policy of free service by the government. It can be justified in case of basic and essential services. The advocates of this principle call is promotional policy and they recommended a concessional water to promote agriculture through irrigation. The promotional policy was appropriate when food production was lagging behind its consumption in India during the initial years of planning. But there has been commendable achievement in our agriculture production in the recent past. Therefore, there is no justification for charging a nominal promotional rate for irrigation water.

Economists normally address the question of right price for water mainly from the efficiency point of view and conclude that as long as excess capacity exists the price of irrigation water should equal the marginal cost of providing it; but whenever a capacity constraint exists the price should be allowed to rise above marginal cost to the point where quantity demanded just equals the available supply. Economic theory clearly states that where marginal cost is continuously falling with the size of the unit, it will remain below the average cost throughout, and any price fixed on the basis of marginal cost under such conditions will not cover the full average cost and will thus necessitates subsidisation. Financing these subsidies by the state will bring about efficiency in the economy which it is argued, may not be

overcome by meeting the subsidies though income tax owing to the likely distortion in allocation of time by the tax payer. Considering the above, the most rational water rate policy appears to be the one under which the water rates are fixed at a level such that the irrigation schemes do not impose a burden on the state exchequer. The projects where unutlisable capacity of irrigation exists, and ancillary facilities are lacking, the farmers are not free to raise to desired crops due to insufficient supply of water. In such cases, water rates should be based on the gross income of the farmers from irrigated crop.

Economics of irrigation pricing also influences the economic development of each region within a country. It is essential to the maintenance of national unity and achievement of satisfactory levels of living. Development and management of water and related land resources on a satisfactory level are essential for the achievement of the required rate of economic development.

The world consists of one-third land and two-thirds water. The rich potential of the world which lies in water is not exploited at all though stray attempts are being made by technologically and economically developed countries for increased agricultural production. The water resources in this one-third land area consists of surface and ground water. Ninety Seven percent of the world's water is contained in the saline oceans. Fresh water for human use, found in lakes, swamps, and rivers makes up only 0.008% of the Earth's water. This shows the scarcity of the usable fresh water on earth. The demand for fresh water continu-

ous to grow with the human population. Within a nation the diversion of fresh water to supply agricultural, industrial, domestic and municipal needs stretches the hydrological systems both natural and man-made, to the limit. Fresh water is unequally distributed among the countries and people of the world. Asia accounts for over large amount of renewable water resources followed by South America and North and Central America. Asia accounts of over one-half of the world's annual water withdrawals. Globally, most water is used for agriculture(about 69%). This reveals the importance of irrigation development which consumes large amount of fresh water.

Most countries facing chronic water scarcity problems, where scarcity is not a problem at the national level, serious water shortages are causing difficulties in specific regions and water-sheds. Human actions may bring about water scarcity in three ways, through population growth, misuse, and inequitable access. The increasing population may induce undue demand on water sources in most of the Asian countries especially in India. The states of irrigation shows wide ranging fluctuations in the percentages of irrigated area to the total geographical area. To compare the performance of India with the Asian countries, India has only 26.03% irrigated area of the arable area.

India is a country of great geographical diversity. The variations in its terrain, temperature, rainfall and soils have closely influenced the cropping patterns and other agricultural activities. There are fifteen agro-climatic regions in the

country. Andhra Pradesh region stretches over the Deccan interior and Eastern coast, covered with alluvial soils deposited by the Mahanadi, Godavari, Krishna, Pennar, and Cauvery. It is a humid region. Rice is the leading crop. Thus, the agro-climatic regions have been delineated with a set objective to prepare suitable agriculture strategy for each one of them. Besides the agro-climatic zones, rainfall in India is dependent in differing degrees on the South-West and North-East monsoons. Most of the rainfall in India takes place under the influence of the South-West monsoons.

The variations in temperature are also marked over the Indian sub-continent. Variations in the temperature and the direction of the monsoon winds bring different amounts of rain to different climatic regions of India. Thus, location, rainfall, nature of terrain, temperature and the availability of irrigation determines the land use pattern of the country.

The reported catchement area of India is 3.05 million sq.km against the total geographical area of 3.28 million sq.km. The major river basins form 83% of the total drainage area and the sources of water supply are significant. Major river basins like the Ganga, the Indus, the Godavari, the Krishna and the Cauvery have a number of canals, tanks and wells. These basins have large storage capacity. The average flow in the river systems of the country has been estimated to be 66,371 t.m.c. and the present storage of water in India has been estimated to be 5185 t.m.c. The present status of water resources use by esti-

mated population of 102 crores, by 2007 A.D, and estimated foodgrain requirement 276 million tonns as against 198 million tonns in 1996-97. The required development in agriculture can, in the long-run, be achieved only through a regionally broad based pattern of growth by devoting sufficient facilities of irrigation and maintaining a continuous flow of economically viable and improved techniques. The ultimate irrigation potential of the country has been estimated to be 113.50 million hectares. Irrigation using surface water is 31.12 million hectares. The future of increased agricultural production lies with more intensive agriculture, especially by increasing the efficiency of the existing irrigation systems as well as spreading irrigation facilities to other hither to unirrigated. The latest estimates indicate that by the year 2000 and 2025, the water use for irrigation will be increased to 63 million hectares and 77 million hectares respectively.

The economy of Andhra Pradesh is largely dependent on agriculture. Blessed with the major river systems like the Godavari, the Krishna and the Pennar and 37 others, the state has a geographical area of 275.07 lakh hectares and a population of about 683 lakhs. The net area irrigated in the state is around 44.7 lakh hectares, 40.6% of wet cropped. The total surface water from the entire river systems of the state is estimated to be in the order of 2,746 t.m.c. The ultimate irrigation potential is assessed at 87.80 lakh hectares. But creation of these irrigation facilities needs large amount of investment.

Investment demand theory requires both the flow and stock approaches. This is to because demand price of an investment good is nothing but the present value of the present and future nominal product of capital. When applied to concrete situations these theoretical issues present economic problems which influence both public and private investments. Public investments are largely infrastructural in nature. In addition, public sector projects are usually subject to some sort of political judgement. In a developing economy, investment is also influenced by other economic and non-economic variables. This is mainly because in many a developing country like India, government plays a very important economic role under the mixed economic principles and national economic plans that have come to be the order of the day and governments' policies and programmes vitally affect economic investment has to assume a dominant role in the process of infrastructural development such as irrigation.

A major determinant of growth in area irrigated by surface irrigation is the volume of public investment in such projects. The rise in real expenditure per hectre of irrigation potential created is the result of three forces., a progressive increase in the number of projects under construction meaning an increasing proportion of funds are spent on the early stages of projects, before they begin yielding benefits; a proportional shift to more difficult and high cost projects as the easier and cheaper opportunities for irrigation development were used up; and

improved standards of design and construction in order to capture greater agricultural benefits.

As irrigation development in India has progressed over the decades, several problems have come up to the forefront. They are problems of paucity of funds which not only restricts the taking up of new projects, but also puts some severe restrictions on operation and the maintenance of the existing surface irrigation systems and the completion of the ongoing and unfinished projects.

Indian irrigation sector is inflationary in nature. This phenomenon is arising from an autonomous rise in the costs. With economic development and improved standards of life, labour cost and cost of materials also tend to increase contributing to rising cost of construction, repairs and maintenance. The data show that wholesale prices of all commodities including food and non-food items, manufactured products have increased 8 times in the country between 1939 and upto 1970-71 at 1939-40 prices. This had further increased to 3 times at 1970-71 prices upto 1983-84 and 2 times at 1980-81 prices upto 1990-91. This has obvious effect on the cost of construction, repairs and maintenance of irrigation sources.

Irrigation investment in the Madras Presidency, the works classed under the productive public works upto the end of 1883-84 were the Godavari delta, the Krishna delta, the Kurnool-Cuddapah canal and the Nellore anicut. Among the diversion works, storage

schemes and multipurpose river schemes, the last two are inherently costlier than the first. Irrigation works in the British period were mostly diversion works across rivers and streams, which involved low cost in nature. Ideal sites were used for construction of cheap diversion works in the British period making it obligatory in the recent years to go in for talking of more complicated sites upstream for locating high dams capable of storing large quantities of water.

Investment in irrigation started during the British era, although it was only in the post-independent period that a concentrated effort was made in developing irrigation networks on a major scale. During the last 40 years of 1951-1990 as much as Rs.262.22 billion has been spent by the country on the development of major and medium irrigation schemes. However, many of the relatively cheap schemes required for developing irrigation in areas with comparatively easy access to water were more or less exhausted during the British period. The Independent government of India took up construction of irrigation schemes, the capital cost of building up such schemes had increased substantially. The working group on major and medium irrigation for the Eight Plan, 1990-95 found that at current prices, investment in irrigation had increased from Rs.1,530 per hectare of irrigated area in the First Plan to Rs.34,924 in the Sixth Plan and to more than Rs.36,800 in the Seventh Plan. Various factors have contributed to this escalation in cost from the late 1970s. A large number of new projects were taken up, during the plan period. This sudden increase in the number of projects undertaken result-

ed in their spreading of the limited funds available for irrigation investment. Projects taken up in the later plans are often on relatively different terrain and involved more geo-technical and environmental and rehabilitation considerations and entailed high costs. It is interesting to note that the average cost of creation of potential per hectare from the Godavari delta system in Andhra Pradesh was just Rs.62 in 1890. The cost of Rs.1418 per hectare in respect of the Kurnool-Cuddapah canal in 1870 was considered abnormal so far as the period is concerned. The average per cost in respect of 22 works executed upto the end of 1900 A.D., in the century worked out to mere Rs.84 whereas for the state of Andhra Pradesh the average per hectare cost of the 3 delta systems excluding the Kurnool-Cuddapah worked out to just Rs.111. During the plan period 1951-95 as much as Rs.54,044 million has been spent by the Andhra Pradesh state on the development of major and medium irrigation schemes, at current prices, investment in irrigation had increased from Rs.4870 per hectare of irrigated area in the first plan to Rs.40,682 in the Eight Plan. Progressive deterioration in the standards of operation and maintenance of sources has been the result of several factors. Before Independence, the government were primarily engaged in the maintenance and operation of the existing irrigation works and took up only a few new works. After Independence, especially since the beginning of planned economic development in the country, systematic exploitation of water resources for purpose of irrigation was taken up on a large scale through construction of dams/storages. Total working expenses in the period 1960-61 to 1986-87(1988-89 prices) ranged between Rs.44.13 and Rs.77.7

per acre. In Andhra Pradesh the working expenses of per acre till 1965-66, it was Rs.1.50. In 1966, it was increased by Rs.4.00 per ace. In 1976-77 to 1988-89 a loss of working expens-es was Rs.876 lakh to Rs.48,555 lakh. In 1989-90, the loss of working expenses which supposed to recover was, Rs.28,032 lakh. This gives the room for evaluation and existing water rates in India as well as in Andhra Pradesh.

The irrigation policy of the British rulers was marked by an apparent change in the fixation of water rates. This was mainly because of strong commercial motivations of the government. The need for rationalisation of water rates arose with the commencement of the irrigation under major river deltas in the early 1850s in the Madras Presidency. The basis of charging of water in the British Period, when supplied by government works, was chiefly the area irrigated. But different systems of charging were in operation in different parts of the Presidency at different points of time. There are fundamentally two main considerations in fixing water rates, namely the consideration of the cost involved in the construction of an irrigation project and the benefits accruing from irrigation to the users of water. Various principles have been laid down for determining the viability of individual irrigation projects. During the 19th century the test for economic soundness of an irrigation project in India was based on chiefly on the direct returns on the investment. Irrigation projects were regarded as 'productive or unproductive according as they yielded a net revenue above or below a certain fixed percentage (4%) calculated

at the "sum-at-charge" ten years after the completion of the project. There was great dissatisfaction with this rate of return towards the close of the past century in India due to the realisation of the fact that there were indirect benefits from irrigation to the community at large. Therefore, the government of India appointed the Royal Commission on Irrigation in 1901 to re-examine the issue. In the context of water rates on the productive works, it should include a charge in the supply of water which would cover primarily the debt charges and overhead expenses. This was again observed by Taxation Enquiry Committee in 1924-25, that it is difficult to evaluate exactly the extra net income of land from irrigation and that this being so the simple thing to do would be to charge a fraction of gross produce of irrigated land as water rates.

The rule noted in section I of the Act of 1865 that "whenever water is supplied or used for purpose of irrigation from any river, stream, channel, tank or work belonging to or constructed by government it shall be lawful for the Government to levy at pleasure on the land so irrigated a separate cess for the use of water. All lands permanently supplied with the means of irrigation for a single wet crop and which are cultivated as **nunjah** and have actually been irrigated for two or more seasons prior to the 18th July, 1863 were classed as irrigated and charged Rs.3 per acre, per annum for water, in addition to their fixed assessment.

Except in the Godavari and Krishna deltas and on the Kurnool-Cuddapah canal, the assessment on irrigated land was consolidated and the share due respectively to `land' and `water' could be only approximately determined. In the Godavari and the Krishna deltas and on the Kurnool-Cuddapah canal, the assessment on irrigated lands was not consolidated, but a separate water rate was levied on the area irrigated owing to the works were constructed by the Government. The rates fixed according to the Revenue settlements, and the difference in the water-rate both in the Godavari, the Krishna and the Kurnool-Cuddapah deltas were due to the variations in duration and supply of water to the tracts. In other cases, they were approximated based chiefly on the application of average dry rates to wet areas, the product representing the land assessment proper and the balance of the wet assessment the share of it was due to irrigation. This was practice till 1869, and the Board of Revenue then condemned the system and introduction of a system of fixed water rates Rs.4 per acre being charged for a wet crop grown on dry land and Rs.2 for dry crops. Prior to 1890, the charge for water was regulated by the class of crop raised, but not by the number of waterings it received. Again in 1896 the Board of Revenue introduced a intermediate rate between wet and dry rates. In 1903, the government faced the problem to implement the intermediate rate between wet and dry because this scale was complex and uncertain in its application, instead the differential water rate system was recommended. Again in 1913 the Board of Revenue condemned the differential system on the grounds that it was inefficient and

pointed out that the fixed rate system caused no serious injustice though open to the objection that, it did not take sufficiently into account the adequacy of supply.

The process of development from 1894 to 1906 was from the simple to complex. In setting a charge for water supplied for irrigation, the factors which may be considered were the area of the land irrigated, the quantity of water supplied and the period during which it was supplied, the soil of the land irrigated and the effect on the productivity or soil caused by bringing water to it, all these factors and more were considered in settlement of the consolidated wet assessment.

Water rates in Independent India vary not only among states but also among canals of the same state. These variations and inconsistencies in water rates in India were attributable to the peculiarities of the particular historical forces which went in their formulation of water rates, which in most cases were the inheritance from either the British or from erstwhile or princely administration. They emerged as adhoc arrangements to be substituted by consistent policies later on. But this substitution was never made and as such, water rates in India have never been fixed on scientific basis.

This issue of the economics of irrigation pricing was received the widest attention in the 20th century especially after Independence. The situation changed, during the period of Five year plans. The attention has shifted from the question of

investment decision to that of recovery of cost. Then there were so many issues come up. One issue the upward revision of water rates in the different Five year plans. The second issue was keeping level of irrigation charges lower. The third was fixation of water rates on the basis of benefit not cost. Fourth was the fixation water rates based on annual income which is equal to annual cost. The fifth issue was the additional net benefit, water rates fixed 25%-40% on additional net benefit, and finally, issues relating to fixation of water rates, based on growth of irrigation facilities and cost recoupment principle and also demand side factors such as full utilisation of available supplies, gross income of the cultivators and farmers ability to pay and supply side factors such as precaution against incurring losses were taken into consideration.

Considering the above principles of water rate fixation, contrary pulls were developed with regard to rate fixation. One emphasised the need to raise rates to recoup all the costs and the other pleaded for keeping down the level of rates to facilitate the full utilisation of newly created capacity.

The systems of irrigation water rates in various states of the country is as diverse as the culture and the people. Rates have been fixed considering a number of factors. Some times without any rationality and objective considerations and they are seldom revised. Major factors leading to variations of water rates are geographical unit, system of irrigation and crop and season. In the states like Uttar Pradesh, the Punjab, Haryana,

Rajasthan, Bihar, Gujarat and Tamil Nadu water rates are charged for actual areas irrigated under different crops. The rates varying with crops, regions and projects. In Andhra Pradesh and other southern states, consolidated wet assessment is levied on lands registered as wet. In general, crop and season are two important factors in deciding the water rate structure. The water rate in Andhra Pradesh is fixed for wet and irrigated dry crop irrespective of crop-wise fixation of water rates.

The central idea of fixation is the supply of water to a number of farms which is the actual service rendered by the government when it constructs an irrigation project. It might, therefore, be expected that the benefits of this operation would be measured by the productivity, prices which the farmers would be willing to pay for the supply of the water. The benefits from irrigation are high and economic rates of return from irrigation are low. The logic is that the productivity and prices of rice were raised by a much larger extent as found in the districts of East Godavari, West Godavari, Krishna, Guntur, Kurnool and Nizamabad. The ratio of water rate to gross value of output was 20.08 during the period 1861-1880. It has been decreasing continuously (i.e., in 1918-19, it was 11% and in 1946-47, it was 8% and in 1966-67, it was 2.6% and in 1995-96, it was 1%). But due to enhancement of water rate by Government Order, 1997, Rs.200 per acre of rice the share of water rate in gross value of output was near to 4%. The gross value output per acre of rice increased through the period by 35 times (1955-56 to 1990-91), whereas water rates increased only 20 times. While the cost of

production increased by 5 times during the period 1970-71 tc 1989-90, whereas water rate share in cost of production decreased by 25%. Thus the low water rates in relation to gross value of output may be low assessment of water rates and providing subsidy in irrigation sector while benefits are well recognised owing to the irrigation development.

Government subsidies may be defined as the difference between the cost of delivering various publicly provided services and the recoveries arising from such deliveries. The subsidy concept is necessary in order to frame the interface between the government budget and public enterprises. Public owned utilities have financial advantages which make it impossible to determine their relative economic meets by comprising their rate structures with privately owned utilities. The lower financial burden allows public irrigation provided at the same economic cost to be sold for less than private irrigation provided. As the difference between the project revenues and project cost must be recovered from other tax sources, low rates shift the financial burden from the irrigation user to the tax payer. Subsidies play a crucial role in stimulating development of any country through increased agricultural production, employment and investment. They are advanced either to promote the use of new inputs or to transfer income in favour of farming community. These are some reasons for which subsidies on inputs are normally preferred. Benefits of government expenditure can be derived by the only in proportion to their use of inputs.

Cost of input subsidies have to be evaluated against the loss of potential benefit if the same amount was invested in creating productive potential of agriculture. It is argued that incentives like subsidies are short-term measures and they are not meant to be substitutes for the long term measures. Hence, a sharp rise in subsidies may cut into the resources available for productive investments. This is what seems to have happened in the Indian context. This is because in country like India where resources are limited, the achievement of any particular objective usually comes at the expense of other competing objective, a major chunk of the increase in resource flowing is being diverted to meet the expenditures originating from high input subsidies rather than making investment in agriculture. The recovery ratio is less when compared to expenditures incurred to particular sector. While agriculture has prospered in many states and has created a large class of prosperous farmers, there is hardly and attempt at raising resources through direct taxation, but receive significant subsidies. The situation where the balance from current revenues at 1984-85 rates of taxes the VII plan is placed at Rs.52.490 million. Budgetary loss on account of operation of government irrigation systems were estimated that the per hectare of canal irrigated area had been increased tremendously (eight fold). The trends show that the actual volume of subsidies was large, amounting to Rs.42,324 crore or almost 15% of the G.D.P. In 1987-88 subsidies in economic services amounted to Rs.25,564 crore or 60% of the total volume of subsidies. The average recovery rate was less than 44%. The cost of these services,

taken along with irrigation and flood control was close to Rs.15,000 crore. Only about 20% of this cost was recovered, leaving a subsidy element to around Rs.11,554 crore. If so much of the country's resources were not spent on these recurrent subsidies, productive investment including investments in irrigation could have been stepped up to achieve and sustain income and employment. The expenditure of the Andhra Pradesh government on subsidies increased from Rs.122.87 crore in 1981-82 to Rs.470.03 crore in 1986-87, registering a compound growth rate of 31.2%. Therefore, these subsidies in irrigation sector might decrease the national dividend, with the mounting fiscal deficit and misuse the input.

SECTION - II

Since the inception of the planning in India, the cost of providing irrigation has been mounting on the government. This prohibitive cost and low returns have discouraged the government to expand irrigation schemes. Many scholars in this field put emphasised the cost and expenditure incurred on the major and medium irrigation schemes neglecting the benefits accrued from them (Gulati, Irrigation Commission Report, 1972). During the British period, the government paid much attention to the cost of providing irrigation and also imposed different rates of cess for different regions considering their cost of production and productivity. Some scholarstouched on minor irrigation and water rates, especially water rates in British India. They noted only irrigation development and water rates under canals neglecting

other factors like productivity, prices, etc (Subramanyam Chetty). These studies highlighted the indegenous irrigation institutions such as **Dasabandam** and **Kudimaramat** during the Crown period(1857 to 1947), and, discussed the effectiveness of the policy implementation and failure and causes of these institutions. One such study partially covered the irrigation water rates (Subramanyam chetti). Another study has touched on water rates in the Ceeded Districts of the Madras presidency. The nature and several systems of water rates were discussed (Subbalakshmi). A significant work on the economics of irrigation and water rates under the Cauvery-Mettur project came out in 1961. This study took the gross value and incremental cost comparison as the basis for fixing the water rates (Agricultural Department, University of Madras). The study of Economis of Water Rates in Panjab and Uttar Pradesh has highlighted the demand side factors as against supply side factors like cost of providing irrigation (Ansari). Demand factors like water availability to an irrigation work, the extent of area, valume of water, cropping pattern and rainfall have been taken into account while fixing the water rates. There was a study on water rates which covered the productvity, prices and gross value of output extensively until 1973 (Andhra Pradesh Irrigation commission Report). And the present study has covered comprehensively the period until 1997. Economic analysis of irrigation pricing has hardly attracted the attention of the researchers in recent times. They tested the investment allocation and financial obligations, i.e., allocation and financial autonomy of irrigation systems and little attention paid to pricing of irrigation (Government of India, Asian Devel-

opment of Bank (ADB), International Irrigation Management Institute (IIMI), Nickum, Kimura and Khan). Another study has emphasised on economic law and water rights and did not give much importance to water rates. This study recommended reforms in the legal provisions for water laws both to purge out the lingering colonial vestiges in the realm of water laws and to make them relevant to the current and future socio-economic requirements. The study further suggested that the water institutions need to be based on water rights system, ecological security, economic efficiency and social equity. This study has ignored the importance of water rates for economic efficiency in irrigation sector (Maria Seleth). Pricing of Irrigation emphasised the relation between rates and water requirements (Vaidyanadhan Committee Report, 1992). The Report also suggested that the cost of recovery should be the main consideration in determining water rates. It also pointed out the necessity of phase-wise rationalisation of water rates which should include crop based rates, volumetric assessment and full cost recovery.

The present study has found that the British government invented a separate and uniform systems of changing the irrigation water to suit the newly emerging irrigation environment. The present study also has analysed the productivity, prices, gross value of output and water rates since 1865 to 1996. The available works on water rates did not give much importance to productivity and prices, gross value of output and water rates.

This leads to the logical conclusion that the socio-economic development in agriculture is dependent on the creation of irrigation facilities, historical and age old know-how and policy of water rates. Gross income of the farmers from the irrigated crops needs to be taken as the suitable basis for the fixation of the water rates in Andhra Pradesh.

The present study indicates that the gross receipts in general have fallen short of the working expenses and it is this widening gap which resulted in the paucity of funds for operation and maintenance, and not to speak of any sizable flow of the new investments. The average cost on cumulative irrigation potential created through major and medium schemes over the period increased the per-hectare development cost due mainly to the poor recovery. The study found that the gross value of output per-acre of rice increased throughout the period by 35 times (1955-56 to 1990-91), whereas water rates increased only 8 times, thus leading to a declining proportion of the share of the water rates in the total output.

The study has also found that the subsidy given to irrigation sector has adversely affected the fiscal budget position and this lack of proper recovery did not give much scope for further investment and development of irrigation. The study suggests the enhancement/re-assessment of water rates to be fixed in such a manner that further development of irrigation sector does not suffer due to resource crunch.

GLOSSARY

Abi	Paddy crop sown at the commencement of rainy season, irrigated by tanks, wells and other irrigation sources.
Anicut	A dam, generally of masonry, to retain or divert running water for irrigational purposes.
Bajra(Mokkajonnalu)	Zea Maise.
Bengal Gram(Shanagalu)	Cicer Arictinum.
Black Gram(Minumulu)	Phaseolus Munso.
Chillies (mirapakayalu)	Cadsicum Annum
Cotton(Pratthi)	Gossypium SP.
Dufassal or Dofasal	Crop which remains on ground for more than six months and is irrigated. When applied at means a double crop a land entitled to raise two heavily irrigated crops or a crop which remains on ground dreariness both the seasons.
Fasaljasti	The charge for water for the irrigation of a second crop irrigated crop on a wet land entitled to raise only one heavily irrigated crop.
Green Gram(Pesarlu)	Phaseolus Arureus.
Groundnut(Verushenagalu)	Araculus Hypogoca.
Horse Gram(Ulavalu)	Dollichose Biflorus.
Inam	Grant of land free of land revenue or at a favourable rate of land revenue.
Jawar(Jonnalu)	Sorghum Vulare
Kharif	Early dry crop harvested in Autumn.
Korra(Korralu)	Setaria Italika
